THE experience of Mr. Berkeley Hill, related in the JOURNAL of January 26th, will, no doubt, elicit other reports on the value of iodoform. I have for a long time employed it in ulcerations of the throat, whether syphilitic or not. When it was first introduced into practice, I applied the crystals to such ulcers in the same way as Mr. Berkeley Hill has used them in primary affections. Finding that, in this form, too much irritation was often produced on the spot where the hard scaly crystals rested, I recommended the drug to be finely powdered, and in this form it may be applied either with a pencil or on bits of cotton-wool. Then came the recommendation to dissolve in ether, which is, in many cases, an excellent plan; but, in others, the fine powder will be found preferable.

In specific ulceration of the soft palate, pharynx, tonsils, or nasal passages, iodoform will often be most efficacious. In those indolent cases which have been believed by able observers to be scrofulous ulceration, but which some of their critics still think due to syphilis, iodoform will sometimes bring about a favourable change when the failure of other means has been most discouraging. As it is equally useful in unquestioned scrofulous conditions, the amendment cannot be used as a diagnostic aid. In ulceration which can only be detected by rhinoscopic examination, the iodoform may be applied by the assistance of the mirror. In this way, some most obstinate cases of ozena and other troubles may be cured. Some other methods of applying this drug locally will suggest themselves and have been for several years taught in my lectures.

I am glad to be able also to support Mr. Berkeley Hill with regard to the use of iodoform internally. I have not often given it in such full doses; but this is, perhaps, due to the difference in the cases in which I have prescribed it. I have very seldom seen it produce much coryza, and have not yet come across iodic acne thus excited. My most usual pill contains one grain of iodoform made up with extract of taraxacum or sarsaparilla.

It should be remembered that, in using any drug in the fauces and nares, a large portion is carried to the stomach; on which account, when applying it freely in these situations, I have not thought it necessary to give pills at the same time.

PROSSER JAMES, M.D., Dean Street, Park Lane.

### NOTE ON IODOFORMED WOOL.

THE remarks of Mr. Berkeley Hill, in the JOURNAL of January 26th, on the "Therapeutic Use of Iodoform", suggest some further applications of this drug than the scope of his observations embraces. It is more especially in diseases of the nose and postnasal region that the proved curative influence of iodoform requires to be more extensively known. In cases of rhinitis, ozena, postnasal catarrh, and hyperplastic deposits, whether simple or syphilitic, iodoform exercises quite a specific influence. As regards the best method of using it topically in these sensitive regions, the objection to the ethereal solution is its extreme painfulness. This defect—a very serious one in the case of delicate females—is due entirely to the solvent employed, iodoform itself having a distinctly anodyne influence on the tissues to which it is applied. Allowing the ether to evaporate somewhat from the sponge or brush employed modifies this unpleasant effect; but even then I have observed patients shrink from its application with expressions of the greatest dismay. I have, therefore, sought for some vehicle for iodoform which, while free from the objections due to the ether, will enable the drug to be maintained in contact with the tissues to be influenced by it. Finely carded cotton-wool appears to supply this requirement; an "iodoformed wool" has been prepared for me by Messrs. Bullock and Co., which has yielded very satisfactory results in practice. Each drachm of the wool contains a drachm of iodoform, with which it is

very intimately blended. For use, it is simply necessary to pass on a probe a small portion of the wool to that part of the nasal cavity which may be deemed necessary. Here it will remain for a period varying from one to twenty-four hours, its presence being unrecognised by the patient. A noteworthy fact about iodoform is, that, unlike most of the substitution-products of the same series, it retains the therapeutic peculiarities of the introduced element, iodine, while acquiring somewhat of the pain-allaying influence of its new associates. This circumstance opens up a wide field for its application as a remedy. From a practical point of view, it would be profitable if other readers of the JOURNAL would contribute the results of their experience of this really valuable drug. EDWARD WOAKES, M.D. Lond., Surgeon to the Hospital for Diseases of the Throat.

### IODOFORM AS A LOCAL APPLICATION IN NASOPHARYNGEAL DISEASE.

THE fact that iodoform, as a remedy in syphilis, has been approved by so accurate an observer, and so competent an authority, as Mr. Berkeley Hill, induces me to recommend it to the profession as a local application in subacute and chronic catarrhal inflammations of the naso-pharynx; a most troublesome class of diseases, and one in which, according to my experience, the use of all other topical agents with which I am acquainted is followed by aggravation, more or less prolonged, of the symptoms it is intended to relieve; that is to say, arrest of the nasal secretion altogether, with consequent obstruction of the passages, or by unduly profuse nasal discharge, which only increases the already existing hyperæmia and thickening. It may be briefly stated that, in such conditions, there is congestion, with granulations, of the visible portion of the pharynx, which, by means of the rhinoscope, can be seen to extend into the naso-pharynx. On anterior examination of the nostrils, so much of the turbinated bones as can be seen will be observed red and swollen; the lower one especially is often so thickened, that nasal respiration is considerably impeded. If, as is frequent, deafness coexists, it will, on this account, be very difficult to pass an Eustachian catheter, and it is quite common for this swelling to be mistaken for a new growth.

Iodoform may be applied in two ways: first, as an ethereal solution (one part of iodoform to ten or twelve of common ether), with a brush or on a piece of sponge or cotton-wool in a suitable holder. The application should be made first to the throat, passing the brush up behind the uvula, and then very thoroughly by another instrument up each nostril. This procedure may, if the mucus be inspissated, be preceded by use of the posterior nasal douche. The only pain is that due to the discomfort of introduction of a foreign body into sensitive passages and to the evaporation of the ether. In any case, the smarting is but momentary. After the application, which should be repeated twice or thrice a week, the mucous membrane will be noticed to be much paler in colour, and to be covered by a thin film of the iodoform. After about six repetitions, the swelling will be found to have much decreased. The second method of using iodoform to these parts is one which may be pursued by the patient; namely, mixed with vaseline and applied with a small brush far up each nostril. This can be done night and morning, or on the alternate days of the stronger application. The form that I employ is five to eight grains of iodoform (with sufficient ether to dissolve it) to one ounce of vaseline.

For the valuable suggestion to use this remedy I am indebted to Dr. R. C. Brandeis of Louisville (at present in this country), who was first led to employ it from observation of its good effects in catarrhal affections of a somewhat analogous nature in the vagina and uterus. It has also been on constant trial by my colleagues at the Central Throat and Ear Hospital for now nearly six months, and I have no doubt that others who try it will hold it in equally high esteem.

LENNON BROWNE, F.R.C.S. Edin., Weymouth Street.

### ON THE USE OF KOUMISS AS A THERAPEUTIC AGENT.

THE remarks of Dr. Lowther in the JOURNAL of January 19th, and the cases mentioned by him, well illustrate the value of koumiss as a remedial agent, and as a form of nourishment almost certain to be assimilated in what otherwise might be considered to be, perhaps, hopeless cases. In phthisis, in the early stages, where capriciousness of appetite or disinclination for any food is a prominent symptom, as also in the laryngeal form of the disease, we possess in koumiss an agreeable and efficacious form of nourishment. In cancer of the stomach or rectum, in the vomiting of pregnancy, in mesenteric disease, in affections of the throat accompanied by dysphagia, in gastric catarrh or

gastric ulceration, koumiss will be found valuable as a remedy and as food. Some patients may consider that it is a somewhat expensive medicine; but, if it be explained that it is also food, and that it is certainly cheaper than wine, this objection is readily overcome.

LEWELYN THOMAS, M.D.

## CLINICAL MEMORANDA.

### THE MARKET HARBOROUGH FASTING GIRL.

THE case of Martha White, so carefully recorded by Mr. Grant, is one of immense importance at a time when the food action of alcohol, opium, etc., is so much discussed. The theory that morphia is both a tissue-preserver and, by its oxidation within the body, a force-producer is almost settled by this remarkable and well-observed case.

I do not see that Mr. Grant need have much difficulty in believing that "it is possible for a person to be kept alive for three years and a half by morphia alone", especially when we remember that the patient under consideration was in a state of complete inability for muscular or mental exertion during most of that time. Many animals live for months in a state of torpor without any food whatever. Morphia produces a condition of the nervous system closely allied to the torpid state of such hibernating animals. When under the influence of the drug, tissue-waste is reduced to its lowest ebb, as is witnessed by the exceedingly small amount of excrement passed during the three years by Mr. Grant's patient. The oxidation of the morphia would doubtless be quite sufficient to supply force for carrying on all the respiration and circulation which such a modified form of animal life would require.

It does not seem more difficult to believe in such a case than in that (recorded by the late Dr. Anstie) of an old man who lived nearly twenty years on a pint of unsweetened gin and a finger-length of toast daily.

The late Dr. Inman of Liverpool records the case of "a middle-aged woman who for two years lived entirely upon opium and gin-and-water. Her chief symptoms were frequent, almost daily, sickness, and epileptic fits three times a week. The bowels were not opened during the whole two years. At her death, the abdomen was so distended as to appear ascitic. This was due to the coating of fat, four inches thick, in the abdominal walls. There was no obstruction in the intestinal canal, and no fecal or other accumulation within it."

The action of alcohol and morphia in such cases is almost identical.

It would be very interesting to know the amount of morphia administered daily in Mr. Grant's case; as also the temperature, pulse, and frequency of respiration of the patient.

JAMES MUIR HOWIE, M.B. Edin., Liverpool.

## SURGICAL MEMORANDA.

### REMOVAL OF FOREIGN BODIES FROM THE AUDITORY CANAL.

AMONG the various means suggested for the removal of foreign bodies from the ear, I see no mention, either in the JOURNAL or in text-books on the subject, of a simple and harmless plan which I have used lately with success. Some months ago, a boy aged 12 was brought to me with a round smooth white pebble in the auditory canal. It could be plainly seen, and had been there for two days, during which time, I was told, repeated efforts had been made to remove it; but their only result was to cause pain, congestion, and swelling of the mucous membrane, which firmly grasped the foreign body, and prevented the possibility of passing any instrument beyond it. I syringed the ear for some time without any good result; and, as his friends were very anxious to have other means tried, I did not like to send him home unrelieved. Having at hand a bottle of the cement known as coaguline, which seems to be a solution of isinglass in acetic acid, I prepared a piece of soft pine-wood, about as thick as a No. 8 catheter, by hollowing the end so as to cause it to fit accurately on the convexity of the pebble. Having now melted my cement by placing the bottle in hot water, and having dried the foreign body with cotton-wool, I covered the hollow end of the piece of wood with the cement, and applied it to the pebble. After waiting for ten or twelve minutes for the cement to set, I made gentle but steady traction, and had the satisfaction of withdrawing the stone firmly cemented on the end of the wood. This plan will obviously be more suitable for round smooth bodies which fill the canal than for small angular ones; but the former are the ones most difficult to remove by any other procedure.

GEO. GRAY, M.D., Castlwellan, Co. Down.

## REPORTS

OF

## MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

### UNIVERSITY COLLEGE HOSPITAL.

#### RECURRENT FIBROID TUMOUR OF THE BREAST.

(Under the care of Mr. CHRISTOPHER HEATH.)

FOR the report of the following case we are indebted to Mr. A. J. PEPPER, Surgical Registrar.

M. A. L., aged 39, was admitted under Mr. Heath, for the third time, on November 6th, 1877. She had received a blow on the left breast in 1862, and to this she attributed the development of a tumour in 1864. This was removed with the breast in the same year, by Mr. Campbell De Morgan. It recurred, and was removed by Mr. Erichsen in 1868; again by Mr. Prescott Hewett in 1870, and by Mr. Heath in June 1876 and January 1877. The return of the growth commenced after the last operation, soon after the wound had cicatrised. The patient has enjoyed good health, and states that none of her relations had been the subjects of tumour.

On admission, she was a thin dark complexioned woman. She presented no signs of constitutional disease, there being no cachexia nor evidence of disseminated growth. Over the region of the left mamma were several extensive cicatrices, the result of previous operations for the removal of the affected breast and recurrent tumours. A lobular mass extended laterally from the left border of the sternum to the posterior fold of the axilla, and, vertically, from an inch below the clavicle to the fourth rib. It completely filled the axilla, so that the arm could not be brought to the side. It was purple in colour; was intimately connected with the skin over it, and was elastic and fluctuating throughout the greater part of its extent. It had not commenced to fungate. The superficial vessels were dilated. Several small nodules were scattered around the main growth. The axillary and supraclavicular glands, as far as could be ascertained, were not enlarged.

On November 14th, ether having been administered, Mr. Heath made an incision across the face of the large tumour and shelled it out. This was repeated with the smaller nodules. In this way, the greater part of the growth was got rid of. No skin was removed. The bleeding was somewhat profuse, and several vessels were tied with catgut ligature. The wound was then syringed out with a strong solution of chloride of zinc, and the edges of skin brought together with carbolised silk, a drainage-tube having been introduced. The operation was performed under the antiseptic spray. Free oozing took place soon afterwards, but this was readily checked by a firm binder. On the third and fourth days, the temperature reached 101 deg. Fahr., and then gradually declined to the normal.

For the first week, the discharge from the wound was quite sweet, but then became somewhat fetid. With the exception of a little bagging of pus, all went on well, cicatrisation, as heretofore, taking place rapidly. The drainage-tube and sutures were removed on the eleventh day, and the antiseptic dressing was changed for boracic acid on the sixteenth day after the operation.

On December 1st, several small nodules of growth appeared, and these, increasing rapidly, were removed on December 14th in the same manner as before. On the 29th, the wound had nearly healed; but now a thickening was noticed about the cicatrix, and a distinct nodule had formed.

The patient (whose general health had suffered but little), not being willing to submit to further operation for the present, was discharged on January 2nd, 1878.

*Structure of Tumour.*—To the naked eye, the aspect was varied, some parts being tolerably firm and striated, distinct bands traversing the section; but the greater portion was soft and gelatinous, of a greyish colour, and mottled here and there with extravasated blood. The centre had broken down into a grumous pultaceous material of a dark red appearance. Microscopically, the growth was found to consist of oval, spindle-shaped, and round corpuscles, characteristic of fibro-plastic tumour.

*REMARKS.*—This case presents the features well defined of the disease in question: the protracted course, the recurrence *in situ* after removal, and the absence of constitutional infection, together with immunity from attack obtained by the lymphatic glands. The longest

interval between the operations required for recurrences of the tumour was six years; the shortest six months; that is, if we omit from consideration the last procedure, which was required rather for continuation of growth after an unavoidably incomplete removal than for a "return" of the affection. Coincident with the increasing rapidity of progress of the disease, we find an alteration in its consistence and naked eye and microscopical appearances. At first, it presented more the characters of a "fibroid", its cellular structure reaching a higher development, but latterly it was in great part gelatinous, or so soft as to have broken down and mingled with blood derived from extravasation into its substance. It is to this alteration in the course of the tumour that Paget has drawn the attention of pathologists, believing it forms a transition stage, as it were, between simple and malignant growths; but the absence of cachexia and the freedom from invasion of the lymphatic glands seem pretty sharply to mark it off from the more virulent disease, although cases have been reported by Gluge and others where a "malignant degeneration" is said to have occurred.

#### ABERDEEN ROYAL INFIRMARY.

CASE OF COMPOUND COMMUNUTED DEPRESSED FRACTURE OF THE CRANIUM: USE OF TREPHINE: RECOVERY.

By J. C. OGILVIE WILL, M.D., Surgeon to the Infirmary.

J. McK., aged 40, labourer, was admitted to the Infirmary on September 29th, 1877, on account of an injury he had sustained by falling from the wall of a house then in the course of erection. The statement supplied by a fellow-workman was, that he fell a distance of thirty feet, breaking the fall twice by coming against some wooden planks and alighting on his head on a heap of stones and gas-cinders. He was unconscious when picked up; but this rapidly disappeared, and, before his removal, he was able to express a strong desire to be taken home; but his wishes were overruled, and he was conveyed to hospital. On examination, a wound about an inch in length, and somewhat semi-circular in outline, was found about the centre of the left parietal bone; there had been a considerable amount of hæmorrhage, but this had ceased before I saw him. On introducing a finger through the wound, a depressed fracture of the skull was readily diagnosed, the forefinger sinking into a pit formed by the depressed portion of bone, while the edges round the depression were well defined. The patient was perfectly sensible, answering questions intelligently, and saying that he would be all right in a few days. He seemed to think that a great deal of unnecessary fuss was being made, and he was very much displeased at having been brought to hospital. His pupils were normal and equal; his respiration regular; his pulse about 80; and he had perfect use of his limbs.

Dr. Pirrie saw the case with me, and elevation of the depressed bone was at once agreed to. The patient having been put under chloroform, and the hair around the wound having been removed, the original wound was enlarged by an incision running from each end, and four or five vessels, which bled freely, were secured by catgut ligatures. When hæmorrhage ceased, and after the wounded surfaces had been well sponged, the extent and appearance of the depression were at once evident. The depressed portion of bone was about the size and shape of a postage-stamp with its corners cut off; it was exactly evenly depressed all round, lying about the eighth of an inch below the normal level of the bone; the overlying edges were even and sharp, and, as the fracture was somewhat oblique in direction, they overlapped the depressed part to a slight degree. In addition to the circular fracture, there was a line of fracture running across the centre of the depressed portion.

On account of the regularity or evenness of the depression, and of the overlapping of the undepressed edges, it was found necessary to make use of the trephine, which was applied, and an elevator inserted. An attempt to raise the depressed portion, without altogether removing it, was made, but it failed; and, upon increased force being applied, a fragment of the fractured bone started out, and, by the repeated application of the elevator, the whole of the broken pieces of bone were removed. The fracture of the internal table was found to be slightly in excess of that of the external plate. The dura mater was uninjured. The bony edges were then rendered smooth, some rough projections being snipped off. The surfaces of the wound were thoroughly cleansed; the edges were accurately approximated and stitched together with catgut; a drainage-tube was inserted, and a strip of lint soaked in cold water was applied.

After operation, the patient's pulse was 102; respirations 22; temperature 99.8 deg. On visiting him at 4 P.M., I was informed that he had slept during the afternoon; he expressed himself as feeling comfortable and free from pain; he had not been sick, and he had swal-

lowed some iced milk. At 9 P.M., he said that he felt well and expected to be all right in a few days. Pulse 98; respirations 22; temperature 100.4 deg.

September 30th, morning. He passed a very good night, sleeping quietly; he had passed urine. There was a slight serous discharge from the tube. Pulse 106; respirations 26; temperature 99.2 deg. A dose of calomel, to be followed by white mixture, was prescribed. 9 P.M.—He was quiet and free from pain. He had slept some hours. The bowels had been freely opened. Pulse 98; respirations 22; temperature 99.4 deg.

October 1st. He had slept well during the earlier part of the night; but suffered considerable annoyance from a cough and pain in the left side of his thorax. The wound was united throughout, except at the point of emergence of the drainage-tube. The discharge was very trifling in amount. All the sutures save one were removed, and also the drainage-tube. Morning temperature 99.6 deg.; respirations 22; pulse 97. Noon temperature 100.6 deg.; respirations 22; pulse 106. Evening temperature 100.1 deg.; pulse 104.

October 3rd. He had a fair night, though somewhat troubled by cough. The discharge from the wound was very slight. Temperature 99.2 deg.; respirations 21; pulse 110. His urine, which had up to this date been normal in reaction and appearance, was to-day found to be alkaline, specific gravity 1030; large deposit of phosphate of sodium. On the following day, the urine was again acid and free from deposit, specific gravity 1027.

From this date, improvement was steady, the patient taking nourishment well; and, excepting on one or two occasions, when he had some transient uncomfortable feelings in his head, but which were unaccompanied by any rise of temperature, nothing occurred worthy of remark. To show how little inconvenience he suffered, I may mention that, on visiting him on October 4th, at an hour when he did not expect me, I found him sitting up in bed writing a letter. The highest temperature registered during his entire illness was that above mentioned on October 1st; viz., 100.6 deg. On October 6th, he got up to stool for the first time, and, on October 20th, he was allowed to leave his bed for a short time; he felt a little dizzy on the first few occasions, but this feeling soon passed off. A few drops of pus continued to exude from the wound each day during the patient's residence in hospital and occasionally after he left, and, though the opening was carefully probed, a small piece of bone, which was subsequently extruded, escaped observation. Consolidation of the parts connected with the opening in the bone soon commenced, and, by the end of November, firm pressure could be applied with a finger without causing the parts to yield.

In the beginning of December, the patient was dismissed, at his own request, and, although the advisability of keeping quiet for a long period was strongly put before him, he could not be persuaded to take that view of the matter, saying that he was quite fit for work, and that he could not afford to be longer idle. He has since presented himself at the hospital on several occasions, and he is apparently enjoying excellent health; and, notwithstanding an evidently free indulgence in liquor, he does not seem to suffer from the effects of the severe injury he sustained, his mental and other faculties being unimpaired.

#### MANCHESTER ROYAL INFIRMARY.

REMOVAL OF THE TONGUE WITH SCISSORS.

(Under the care of Mr. LUND.)

THE patient, a married woman, aged 34, had suffered from a growth in the right half of her tongue for fifteen weeks. Ulceration had extended beyond the substance of the tongue into its connections with the jaw, rendering the prospect of benefit from removal not of a very hopeful character; the pain, however, and other kindred considerations, overbalanced every objection, and the tongue was condemned for removal. Mr. Lund, before operating, observed that he was going to proceed by following the example of Mr. Whitehead and remove the tongue by scissors through the mouth, an operation which appeared only to require a certain amount of manual dexterity in order to obtain the best features of any of the recognised modes of extirpating the tongue. After explaining the details of the operation, Mr. Lund commenced by passing a ligature through the tongue, which he intrusted to his assistant on the patient's right hand, with a request that he would continue to draw the tongue firmly outwards and upwards, as by this means he would afford him the most important aid in the operation. The patient's mouth was maintained well open with Ferguson's gag during the operation. The tongue was then deliberately removed by successively snipping with ordinary scissors through all its attachments to the jaw and hyoid bone. The hæmorrhage where the two main arteries were cut was undoubtedly sharp,

and would speedily have proved decisive in the absence of coolness and decision. Both vessels were tied with catgut, and no bleeding subsequently took place.

After the tongue had been removed, Mr. Lund gave Mr. Whitehead an opportunity of putting into practice his suggestion that a silver wire ligature should be attached to the remaining portion of the glosso-epiglottic ligaments; a procedure which, he anticipated, would prove of advantage in the after-treatment of such cases. By means of such an aid, it was expected that the floor of the mouth would not be left so entirely beyond the command of the surgeon should secondary hæmorrhage take place; and further, it would enable the surgeon to draw forwards and upwards the posterior floor of the mouth, and so fix it by attaching the ligature to the teeth or even outside the mouth, and by this means secure a tendency for the secretions to drain outwards, in preference to their gravitating down the larynx, with the constant risk of being drawn into the trachea, rendered less under the protection of the epiglottis in consequence of the operation. In the after-progress of the case, these speculations proved to be not unfounded; for although no secondary hæmorrhage took place, the possible utility of the wire ligature in such a case was demonstrable, and any inconvenience occasioned by the presence of the wire in the mouth was of too trivial a nature to demand consideration. The patient necessarily suffered pain after the operation; but when the pain, which was obviously of a neuralgic character, and in a great measure was due to the patient having been injudiciously placed in a bed where there was a down draught, was excluded, it could but be admitted that there was comparatively less than that which results from any of the other methods of removing the tongue.

The recovery was uninterrupted; the convalescence, and consequently the period of inconvenience, showed a most marked and favourable comparison with that of any other operation. The mouth, on the eighth day, exhibited a healthy granulating surface, and no ill effects from the operation were either apparent or apprehended.

## REVIEWS AND NOTICES.

TWO LECTURES. 1. Lectures, Books, and Practical Teaching. 2. Clinical Instruction: being Introductory Addresses delivered in the University of Glasgow and in the Western Infirmary, Session 1877-1878. By W. T. GAIRDNER, M.D., Professor of Practice of Medicine in the University of Glasgow, etc. Printed for Private Circulation. Glasgow: J. Maclehose. 1877.

In two introductory lectures delivered in the University of Glasgow and the Western Infirmary, Dr. GAIRDNER gave the results of his experience as to the best methods of imparting medical instruction and the relative value of the different forms of teaching.

Referring to the character of systematic lectures, so-called, two distinct varieties are described: those which are as good as a book, no better and no worse, except that they give the student the trouble of attending them and of taking notes to assist his memory; and those in which the living teacher endeavours to render himself of value to the student. Medical teaching should always be such as to convey the facts and doctrines of modern medicine, and such as is fitted to impress them upon the minds of the students and to inspire them with the spirit of modern medicine.

In the modern era of investigation, with our present methods of physical observation, a change has become necessary in the methods of conveying instruction.

Dr. Gairdner thinks that the chief advantage of oral lectures over a book consists in the greater amount of thoughtfulness engendered in the former case, while at the same time the opportunity is afforded of testing the statements and questioning them. After all, the utmost that the student can do in the course of his ordinary curriculum is to learn well a few of the better known and more clearly established facts and principles, and acquire such mental training as may prove a fitting soil for the future teaching derived from reading, experience, and social and professional intercourse. The teacher can help to imbue the mind of the student vividly with what is least doubtful and most important, and train the mind when to acknowledge ignorance and suspend judgment, or form only provisional conclusions; how to appreciate at once, with the least amount of delay and disturbance, every important symptom and physical sign bearing upon a case, and how rapidly to sum up in his mind all the available evidence as to the natural termination of similar cases, the probable causes, the probable results of remedies; and thus arrive at a thoroughly reasoned, but not always proved, conclusion as to what ought to be done in each individual case. The student's mind would thus be opened to future enlightenment. It appears

obvious that these processes of mental training can be carried out far better by a living man than by any book.

Speaking of the methods of clinical instruction, Dr. Gairdner refers to the evils arising from a want of subdivision of labour, especially in the conduct of out-patient departments, the overcrowded state of which often leads to bad habits of inaccuracy and want of thought. A multitude of cases thus rapidly seen tends to render the mind sterile rather than experienced, so that the student is trained to become the veriest empiric—a mere man of routine.

LA RÉFORME DU CASERNEMENT DANS L'ARMÉE FRANÇAISE. LES BAINS-DOUCHES. Par M. C. TOLLET. Paris. 1877.

THE necessity for improving the construction of the barracks in which the troops are lodged in France, and so reducing the sickness and mortality among them, has recently attracted very earnest attention in that country. Among others, a distinguished engineer, whose name appears above, has been prominent in describing the "Barracks of the Future", and in advocating, as guiding principles for their construction and for that of military hospitals, that they shall consist of one-storeyed buildings, that they shall have an ogival outline, all angles being suppressed, as the form presenting the least impediments to the freest movement of air about them from whatever quarter the wind may blow, and that they shall be composed of incombustible materials. M. TOLLET professes to have taken from the English system all that is excellent in respect to housing the troops in small separate groups, as in hut-barracks, and to have borrowed from the Americans principles of simplicity and lightness of construction, at the same time guarding himself against imitating their employment of wooden barracks, which are perishable and inflammable. These objectionable circumstances are avoided by the skeletons of the barracks being made of iron, and this framework filled in with various materials of an incombustible nature. Barracks were erected on this system for a portion of the 8th corps d'armée in 1875; at Bourges, for two regiments of artillery; at Cosne and at Autun, each for one regiment of infantry. These barracks have been occupied since May 1876, and, it is said, with the result of the average sickness of the troops quartered in them being reduced to one-half of the previous ratio. At the same time, there was a very considerable gain in the original outlay for their construction, as compared with the cost of barracks of the ordinary forms.

M. Tillet is now advocating the addition of warm baths to all barracks, and he has prepared plans and estimates for a system which he considers to be the most simple, the most easy of application, and the most economical which can be devised. We must refer the reader who may be specially interested in the subject to the plans and drawings attached to M. Tillet's paper, which will be found in the form of a pamphlet, published on the 1st of November last, for the Société Française d'Hygiène, by Messrs. Delahaye of Paris. A description without the drawings would fail to convey an adequate notion of the form and arrangements of the bath-houses proposed by M. Tillet. He adopts the douche-bath as the most suited to soldiers for the purposes of ablution, and, at the same time, as requiring the least expenditure of water. Separate cabins are supplied for the bathers in the proportion of two for every hundred troops, together with the necessary compartments and fittings for deposit of clothes, materials for washing, etc. The author gives various reasons for supplying warm instead of cold water for purposes of ablution in barracks. Twenty-five litres of water are allotted for each douche; and, owing to the manner in which the flexible outlet-tubes are arranged, it is easy for a man to direct the water over any part of his body at pleasure, and at any desired rate. M. Tillet estimates the original cost of construction of the whole bath establishment, with its fittings, at the rate of ten francs per soldier; and the cost of repairs, maintenance, attendance, and fuel at one hundredth of a franc for each douche bath—an outlay which, as M. Tillet says, is truly insignificant in regard to the cleanliness and comfort of the individual soldier, and the sanitary saving that would result to the army at large.

## COLUMN FOR THE CURIOUS.

JABORANDI.—In Boyle's treatise *The Usefulness of Experimental Philosophy*, he states, on the authority of Piso, "that an infusion of the root jaborandi rescued, to his knowledge, many from an imminent death, who had eaten several sorts of poison; and this, after the whole tribe of European alexipharmics had proved unsuccessful". This essay was published in 1663. I copy the extract from the complete edition of Boyle's works published in 1738 by Peter Shaw, M.D.

F. W. COCK, JUN.

## BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, FEBRUARY 9TH, 1878.

### PHYSICIANS, PRACTITIONERS, AND FEES.

THE large number of letters which we continue to receive on this subject, as well as the correspondence and the articles lately published in the *Times* and other newspapers, show the great amount of interest felt in the question both by the profession and by the public. The discussion seems, on the present occasion, to have originated in the comparatively trivial fact that it is not customary for medical men, in sending in their bills, to furnish an account of the items of attendance. We had thought that this custom obtained in the interest of the patient rather than of the doctor. It would often be neither pleasant nor profitable to the individual members of a family that the reasons for medical attendance upon them should be submitted to the inspection of all the rest. That small portion of the public who complain of this omission are probably the same as those, unfortunately to be found in every practice, who require their bills to be rendered five or six times, at intervals of six months, before they think fit to pay them. It would, no doubt, be too much to expect such persons to consider that this repeated rendering of accounts is itself a sufficiently arduous labour, without compelling the addition of writing out the items every time. That this enormous addition to labour, as it would compel extra clerical assistance, would probably add to the cost of the medical attendance, is of no moment to that portion of the public who as often as not forget to pay their bills. But this is the smallest part of this question, and is in itself of little importance, since no doubt medical men, who are asked to do so, will offer no objection to furnishing the items of their accounts; and had this been all, we should not have troubled our readers with any remarks on this matter. The settlement of some of the other questions touched upon in this correspondence is, however, not so easy a matter, while some of them involve points of very great difficulty.

What, for example, is a consultant; and what is a practitioner? Is the distinction a real one to-day; or is it not rather a survival of the time when the surgeon of old, who was the father of the present general practitioner, following his calling of a barber, was considered, and justly, quite unfit to associate with the educated gentleman in attendance on the Court or on some great noble? To our mind, a consultant ought to mean a medical man who sees patients only in consultation with their ordinary medical attendant; and, if this definition be accepted, we doubt whether any specimens of the genus exist. Practically, so far as we can see, a consultant is a gentleman no doubt, as a rule, of superior general culture and knowledge of his profession, who sees patients at his own house at stated hours, and who is quite willing to visit them at home if requested to do so; it being understood that he confines his practice to medicine or surgery, as the case may be; and that the rate of his remuneration is higher than that usually accorded to the practitioner. He is, in fact, a practitioner (though exclusively medical, surgical, or obstetrical) among the rich, or among those who are willing to pay a guinea or more for each consultation or visit. As, in point of fact, the ordinary general practitioner, so called, finds the bulk of his work in medicine and obstetrics, the difference

between him and the consultant really resolves itself into a difference of fees. We are not objecting to this. The difference of remuneration generally corresponds with the superior value of the opinion of the consultant as compared with that of the practitioner, though some of the latter offer advice at their own lower rate quite as valuable as the highest possible.

The term practitioner, again, is one which covers a very wide range, not only as to fees, but as to the real value of the advice given. This will not appear remarkable, if it be remembered that the grade practitioner is constantly furnishing additions to the ranks of consultants. Some of the names which deservedly stand highest in the consulting world were formerly to be found among practitioners: a fact which goes far to explain the differences in value of the advice of practitioners of different degrees of standing. It is not to be expected that a practitioner who in the course of a few years will be reckoned among consultants proper, and who is even now, let us suppose, consulted from time to time by his professional brethren, will take fees as small as those which a beginner is glad to accept, or as small as he himself was satisfied with ten or twenty years before. These considerations are strengthened by the way in which a man in general practice comes to devote his attention to a particular subject, and by-and-by comes to be regarded by his professional brethren and the public as an authority upon that subject. As his special work increases, his reputation becomes more and more established; and thus, the reputation increasing the practice, and the practice in turn increasing the reputation, the point is at last reached when the medical man may confine himself to that department in which common consent and special attention on his own part make him an acknowledged authority.

This being the course of things, there must always be men who are partly consultants and partly practitioners; and we venture to think that it is well both for the profession and the public that it should be so. For this reason, we dissent entirely from those of our correspondents who, either by implication or avowedly, wish to maintain a hard and fast line between practitioners and consultants. This hard and fast line would at once be seen to be untenable, if it were asserted that a practitioner like the late Dr. Anstie was not entitled to the same rank in the profession as some of our own consultants whose names will never be mentioned after their own generation. There are some questions now demanding settlement—questions of the greatest importance—which the family doctor, as distinguished from the consultant, has special facilities for determining. We are inclined to think that, but for the fact that it has been taken for granted that the family attendant need not be a highly cultivated or scientific man, some of these important questions would be nearer their solution than they are at present. Who, for instance, ought to be so competent to deal with that phase of evolution which goes under the name of heredity as the family practitioner, who knows the history of his patients by personal observation over many generations, and whose father, had he been trained to observe them, could have furnished particulars which his own observation could not cover? We venture to think that the waste and misdirection of observation, from want of sufficient training in the family attendant, have caused a loss which is even now sensibly felt in the scientific thought of the time. Nothing will tend so much to perpetuate and aggravate this want as the continued disability which prevents the practitioner from rising to the highest grades of his profession. One of our correspondents actually goes so far as to assert that a quasi-consultant who does some general practice deserves to lose his fees when he allows the visits to "run on". By what principles of honesty, or even of etiquette, he justifies such an assertion, we are at a loss to discover. That regulation of the College of Physicians which prohibits its Fellows from suing for fees was intended, not to cover the dishonesty of a fraction of the public, but to raise the standard of the medical profession: and it is, therefore, the more to be desired that

such an amount of good feeling should exist on the part of the public as to render an appeal to law altogether unnecessary.

The differences to which we have referred in the value of the advice of different general practitioners justifies the different arrangements which they are willing to make with the public. So long as a differential value of skill exists, a differential scale of payment is a necessary consequence. This must evidently be a matter of private arrangement between the doctor and his patients. Some excellent observations and suggestions have appeared in these columns, in a paper written on this subject by Dr. Ogle of Derby. Dr. Ogle deprecates payment, either by the medicine supplied or by the number of visits paid, and is very anxious that the doctor should become the agent of preventive medicine in ordinary medical practice. In order to the attainment of this end, he advocates the annual payment of a sum, to be agreed upon, which shall cover all ordinary attendance. Such an arrangement obtains, we believe, in many parts of the Continent, and is by no means unknown in this country. Under it, the medical man can be of immense service to his patients by periodic visiting, without risking the unpleasant accusation of purposely running up unnecessary bills. Ordinary work is defined as including "all attendances for which the request has been made at an early hour of the day, say by the time of the first postal delivery; also all visits made by members of the family to the doctor at his own house, when he is 'at home' for consultation". Night visits, Sunday visits, urgent summonses for the convenience of the patient, etc., to be paid for extra. This arrangement makes the interest of patient and doctor identical, and has been found to work well where it has been tried. In order to carry out the preventive portion of Dr. Ransome's scheme, which he adopts, Dr. Ogle suggests the following. "All *per annum* sums of, say under ten guineas, to be paid to a common fund. The respective family doctors to receive, say two-thirds of this; the remainder to be devoted to the general purposes of the Sanitary Association, available for payments for medicine, organisation of hospitals and convalescent homes for the well-to-do, registration of disease, purchase of expensive instruments, and the like." It would be well if these suggestions, particularly the former, could be carried out. The latter is unfortunately open to the objection that medical men would be called upon to do for the public what the public ought to do for themselves. It would be too much to ask any other profession than the medical to part with one-third of their fees for charitable purposes; though the enormous amount of gratuitous work already done by doctors in hospitals, etc., makes this proposition seem less anomalous. The sacrifice might, however, be worth making temporarily, since the public, finding the advantages of the arrangement, might continue it at their own cost. The former part of Dr. Ogle's scheme would, if carried out, for ever put an end to this unseemly and paltry squabble about fees, and would tend to make the relations between the profession and their patients more satisfactory. We should be glad to hear that the British Medical Association had taken some steps towards the carrying out of these or similar suggestions, since we are convinced that their adoption would be beneficial to all concerned.

#### THE DUBLIN BRANCH OF THE ASSOCIATION.

THE first annual meeting of the Dublin Branch has been held under auspices which are promising of the continued growth and increase of usefulness of the Association in Ireland. Although only a Branch meeting, it became an occasion of considerable importance to the interests of the Association and the profession at large, from the fact that it was presided over by the most eminently representative men in the departments of medicine and surgery in Ireland. The heads of all the great medical corporations of the metropolis of Ireland and of the Irish Medical Association were present, including Dr. Hudson, the Physician to the Queen in Ireland; Mr. George Porter, Surgeon to the

Queen in Ireland; Dr. Gordon, President of the King and Queen's College of Physicians in Ireland; Dr. McDonnell, President of the Royal College of Surgeons in Ireland; Dr. Darby, President of the Irish Medical Association; Professor Haughton, Medical Registrar of Trinity College, Dublin; and a number of other persons of official and scientific eminence. Nearly all the great names in medicine and surgery which adorn the metropolis of Ireland were represented on the list. The President of the British Medical Association, Dr. Eason Wilkinson of Manchester, showed his sense of the importance and interest of the occasion by attending. Dr. Curtis and Dr. Macnaughton Jones, the President and ex-President of the South of Ireland Branch, the first in the order of chronological formation of our Irish Branches, accepted the invitation to be present; as well as Dr. Cumming and Dr. Moore of Belfast, the President and Honorary Secretary of the new North of Ireland Branch, the youngest, but, we have good reason to hope, far from being the least promising, of the Branch organisations of the Association. Among the visitors, also, the Branch had the satisfaction of welcoming Dr. Jacob, who inherits a historic name in Ireland, and who has continued some of its best traditions by constant attention to and unflinching support of the interests of the profession in Ireland.

At the general meeting, Dr. Hudson delivered the address which we have the advantage of reproducing to-day, and which will, we believe, be considered by all our readers worthily to uphold the reputation of the leaders of the Irish school of medicine for philosophic thought and eminent clinical sagacity. Of such a meeting, held in the fine hall of the College of Physicians, in the presence of the admirable statue of Stokes which adorns the College and faced the speaker as he delivered his address, it was impossible but that the memory of the words of Stokes, and of his attachment to the Association, should have rested; the welcome with which he greeted the Association in Ireland in the name and as the leader of the whole profession; the frankness and heartiness with which he recognised it as an Association altogether peculiar in its organisation, aiming at objects which are good, and consequently are great; seeking the unity of all the members of the profession in the three kingdoms in a series of independent but yet connected organisations; aiming at the advancement of the profession by labours of love on the one hand and by labours of science on the other. These words and that influence were living in the minds of our Irish members, although the voice that uttered them is stilled for ever.

The speeches of Dr. Little, the Vice-President of the College of Physicians, and the accomplished editor of the *Dublin Journal of Medical Science*, of Dr. Darby, the President of the Irish Medical Association, and of Dr. Jacob, in responding for the Irish press, were specially marked by a warm appreciation of the importance of the British Medical Association as an organisation of which the objects are faithfully reflected in the words of Dr. Stokes, which fosters all local efforts, while it endeavours to combine the whole profession for interests of the highest kind which are common to all medical men. The words of Dr. Wilkinson, accurately responding to that sentiment, and worthily expressing the opinions of the Association at large, were warmly received; and his presence was cordially welcomed as a testimony to the sympathy which the Association at large feels for its members in Ireland. Within the last ten years, the number of our Irish members has risen from a score or two to upwards of five hundred, representing, we believe, more than a third of the total strength of the medical profession in that country. It is only within the last fifteen months that we have succeeded in persuading our Irish members of the importance of organising themselves in Branches, so as to secure the full benefits of association, and to take their just share in the general councils of the Association, and to assume their rightful influence in the conduct of its affairs and in directing its operations.

The initiative in forming the first Irish Branch is due to our brethren in Cork, and especially to the efforts of Dr. Macnaughton Jones in that city. The Association, however, owes a debt of gratitude to Dr. J. W.

Moore of Dublin, for many years of faithful courtesy and gratuitous services as its Honorary Secretary for Ireland since the Dublin meeting of 1867, during which it had no Irish Branches. Especially, also, are acknowledgments due to Dr. G. F. Duffey, to whose energy and administrative capacity are mainly due the formation of the Dublin Branch and the eminent success which attended its first annual meeting. He must have felt himself largely requited by the brilliant success of the meeting and dinner. Eighty members attended the banquet, and probably so large and eminent an assemblage has never before graced a Branch meeting. Forty new members were elected to the Branch in the course of the day. It now numbers one hundred and forty-seven members, and there is every reason to anticipate that that which has been so successfully commenced will be carried on with corresponding prosperity and advantage. The programme of the Branch and its sphere of usefulness was accurately traced in the report which Dr. Duffey presented. The Association tends every day more and more to embrace the whole strength of the medical profession in the three kingdoms. Thus united, and acting through the local councils and by the representative central executive, the profession is attaining power and influence, which it will behave all who are interested in it to see used with the highest regard for public and professional good.

#### THE PATHOLOGY OF DROPSY.

MM. COHNHEIM AND LICHTHEIM recently published a paper in Virchow's *Archiv* (Band lxxix), in which they showed, by a series of experiments, that, while it was possible to produce the highest degree of hydræmia without causing anasarca, yet this result followed very slight irritation of the skin of the animals; and they inferred that some degree of change in the vessels of the skin and cellular tissue was a necessary factor in its production. Writing from another point of view, Professor Senator of Berlin gave an account of his clinical investigations on the importance of the functions of the skin in relation to the kidney in the same periodical (Band lxx), in which, it may be remembered, he undertook to refute the common prejudice in favour of free cutaneous transpiration, which seemed favoured by the results of varnishing the skins of dogs and other small animals; death in these cases, preceded by albuminuria and phenomena of uræmic poisoning, having been generally observed. Senator painted his patients with various substances—collodion, tar, etc.—and found them suffer no inconvenience from the process; indeed, they seemed to consider it rather beneficial, for one experiment was terminated by the patient asking for his discharge as quite recovered. With reference to these relations, Dr. O. Lassar, who is, we believe, assistant to Professor Cohnheim, reports a very interesting case in the January number of Virchow's *Archiv*. It was that of a man who had been under the care of Dr. Friedländer, and whose body came to the pathological theatre with the diagnosis "nephritis". During life, his urine had been very albuminous, and contained hyaline and granular tube-casts. The body was extremely oedematous, and in certain parts the epidermis was raised in little scabs containing clear thin not coagulating fluid. The section showed dropsy of the cavities and oedema of the lungs, but no disease of any organs to account for the dropsy; notably, the kidneys were macroscopically and microscopically free from lesion. On inquiry, however, it turned out that the patient had dated his illness to the use of petroleum, which he had rubbed over his skin to free himself from scabies; he had done this for four days, and after a week he noticed a swelling of the feet, which spread over the abdomen and thorax; after about a fortnight, it disappeared, but returned in eight days to remain up to his death. During his stay in the hospital, his pulse had been noted as small, empty, and of low tension; the blood-corpuscles were few but relatively normal in proportion; his temperature was normal. Histological examination of the skin showed localised areas of inflammation characterised by a small-celled growth spreading along the course of the blood and lymph-vessels, and nuclear

proliferation in all the layers of the cutis. According to Dr. Lassar, in this case the skin-affection was primary, and the cause not only of the oedema, but of the albuminuria as well, the renal affection being purely functional. The examination of the kidneys is stated with precision; the absence of all appearances capable of explaining the phenomena, including congestion, are so carefully noted, the only abnormality being a trace of fatty degeneration of the epithelium, which is of no importance, that it is hard to deny the functional nature of the albuminuria; but its mechanism is quite unexplained, the absence of congestion of the kidneys and the low tension of the radial pulse negating the idea of simple filtration under pressure. But we cannot see why it should be considered secondary to the skin-affection, so long as we have another at least as probable cause, namely, the direct influence upon the kidneys of the absorbed petroleum; from what we know of the influence of allied compounds, we are justified in supposing that this may have been the case. We are not told whether the quantity of urine passed was below the normal or not; this omission is serious; because, if it were, we think there would be quite sufficient reason to regard the dropsy in this case as secondary to, and caused by, the non-elimination of water by the kidneys. Until this point is cleared up, we see no reason for giving up this view of the mechanism of dropsy, founded on so many clinical facts, and which has recently found such an able exponent in Professor Bartels. If dermatitis *per se* could produce anasarca, we ought to see it frequently in the cases of extensive superficial burns or scalds; in these cases we have never found histological evidence of renal changes or any anasarca.

#### JUDICIAL POST MORTEM EXAMINATIONS IN SCOTLAND.

A CASE has recently occurred in Scotland which raises a question respecting *post mortem* examinations in inquiries before the Procurator-Fiscal, similar to that which frequently presents itself at coroners' inquests in England. Who is the proper person to conduct a *post mortem* examination in a case of sudden death? By whom should he be nominated or selected? The facts in the Scotch case are very simple; but the correspondence relating to them is so lengthy, that we could not possibly find room for it in the body of the JOURNAL.

Dr. Angus Fraser of Aberdeen, being the family medical attendant, was sent for one morning to see the deceased. He found him dead in bed. On inquiry, he was informed that the man had gone to bed in apparently good health, and had been found dead by his wife, who was sleeping by his side, a short time before the doctor saw the body. He was sent for to verify the death. Dr. Fraser looked upon this as an ordinary case of sudden death from natural causes; in other words, there were "no facts or rumours connected with the death, pointing to criminal blame, or a notable absence of the characteristics of death from natural causes". He, therefore, did not think it necessary to report the case to the authorities, so that a certificate might be obtained for a judicial remit; in other words, he considered a judicial inquiry into the cause of death unnecessary. For his own satisfaction, however, he thought it would be well to make a *post mortem* examination, to ascertain the cause of death. This was assented to by the widow, and it was arranged that it should be made two days after death. In the meantime, the Procurator-Fiscal, who appears to have received information of the sudden death from other sources, issued a remit or an order for a *post mortem* examination to Dr. Ogston, Professor of Medical Jurisprudence in Aberdeen. The *post mortem* examination was made by his son, Dr. F. Ogston, on the day after death, no doubt with the sanction and under the superintendence of the professor; and the result, it is to be presumed, quite confirmed Dr. Fraser's view that the man had died suddenly from natural causes; and there the matter dropped.

If this case had occurred in England, it would probably have been carried a stage further. A public inquest would have been held in some public-house, a jury of twelve or fifteen neighbours would have

been assembled, and the evidence of the widow and the two doctors would have been formally taken. The verdict would have been the same—death from natural causes; and it is precisely these additional proceedings in English practice which are quite unnecessary, and which it is desirable to abolish in all cases of sudden death from obviously natural causes.

Dr. Fraser complains that the *post mortem* examination was handed to another; but a Procurator-Fiscal, like an English coroner, has an undoubted right to nominate whom he pleases to conduct the examination, *i.e.*, provided the person nominated is a legally qualified practitioner. Of the competency of the gentleman nominated in this case by the Procurator-Fiscal there can be no question; Dr. F. Ogston, who acted under his father's directions, obtained his qualification to practise in 1873. On this occasion, Dr. Fraser had seen only the dead body of the man, and had not recently been in attendance upon him. It seems also, from the correspondence, that he had not communicated in any way with the Procurator-Fiscal. Had he informed the Procurator-Fiscal of the abovementioned circumstances, this gentleman states in one of his letters that he should very probably have arranged with him either "to examine the body or to be present at its examination".

After carefully reading the whole of the correspondence, we cannot perceive that the Procurator-Fiscal has exceeded his duty or been guilty of any neglect or omission. He simply exercised that power of selection which the law gives him *ex officio*, and he issued the remit to a gentleman in every way competent to conduct the *post mortem* examination. The result confirmed the justice of Dr. Fraser's opinion.

It is reported that small-pox is still raging severely at Cawnpore and Lucknow. Half of the Buifs are out in camp, owing to an epidemic of the disease in the former station.

A TELEGRAM from Mysore states that the census shows that 25 per cent., or a million and a quarter, died during the famine, and that 35 per cent. of the poor classes have disappeared.

DR. J. RUSSELL REYNOLDS, F.R.S., Physician to University College Hospital, is gazetted Physician to the Queen's Household, in succession to the late Dr. Francis Hawkins.

DR. LAMSON, chief Surgeon at Bucharest of the Sick and Wounded Russian Soldiers' Relief Fund, has received the decoration of the Star of Roumania, in recognition of his services to the sick and wounded.

MR. J. E. A. STEGGALL, the son of a well known member of the profession in London, who last week achieved the proud position of second wrangler at Cambridge, has been adjudged the first Smith's prize for pure mathematics, defeating the senior wrangler in the competition for that high honour.

ON the 13th instant, at 8 P.M., at the rooms of the Society of Arts, John Street, Adelphi, Mr. W. Eassie will explain the systems of cremation now in regular use in various parts of the continent, and will illustrate his paper by diagrams and also by models of crematory apparatus which have been collected by him in Italy and Germany.

ON Tuesday evening last, Dr. B. W. Richardson delivered the first of a series of four lectures, to be delivered on successive Tuesday evenings at Devonshire House, Bishopsgate Street Without, on the subject of the practice of abstinence from alcoholic drinks, with special reference to the difficulties of learning to abstain. The lectures are delivered under the auspices of the National Temperance League.

AT the distribution of the prizes for 1877 by the French Academy of Sciences on January 28th, the Montyon prize in physiology was awarded conjointly to Dr. D. Ferrier and MM. Carville and Duret. The Bréant prize (£4,000) for the discovery of a cure for cholera was not awarded, but the interest of that sum was given to M. Rendu, for several memoirs on etiology.

DR. HENRI GUENEAU DE MUSSY was last week elected a Member of the Academy of Medicine in Paris, in the Section of Hygiene.

#### THE PRINCESS OF WALES.

OUR attention having been drawn to certain statements respecting the health of Her Royal Highness the Princess of Wales, we are very pleased to have authority to state that Her Royal Highness' health was never better than at the present time, and that all reports to the contrary are without foundation.

#### CARDIFF MEDICAL SOCIETY.

THE annual meeting of this Society was held on January 31st. The report of the Committee showed that the number of members was twenty-four, being an increase of three over the number last year. Seven meetings have been held during the year; of which two were special, having reference to an alleged charge of cruelty against one of the members, and the censure of another by the Local Government Board. Ten papers had been read at the meetings. The following officers and Council were elected. *President*: W. T. Edwards, M.D. *Vice-President*: A. P. Fiddian, M.B. *Committee*: The President, Vice-President, and Secretary; M. G. Evans, M.D.; J. Milward, Esq.; H. J. Paine, M.D.; W. Price, M.B. *Honorary Secretary and Treasurer*: A. Sheen, M.D.

#### DEATH OF DR. PEASLEE.

WE regret to hear of the death of Dr. Edmund R. Peaslee, the distinguished American gynaecologist. He died at the age of 64, in New York, on January 21st, of pneumonia, after a week's illness. Dr. Peaslee had gained a high reputation in ovariectomy, on which subject he published some years ago a treatise of much value. He had been engaged in teaching anatomy, surgery, and obstetric medicine in various institutions since 1842; and from 1874 up to his death was Professor of Gynaecology in the Bellevue Hospital Medical College.

#### ANOTHER FASTING GIRL.

WE have it on the authority of a provincial paper, that another Welsh fasting girl has come to light. Her name is Morgan. She is about fifteen years of age, and is said not to have eaten nor drunk anything since the 30th of October last.

#### PREVENTION OF DISEASE.

DR. SAUNDERS, the Medical Officer of Health to the City of London, in his recent report, says, in reference to cases of contagious disease, many of them had been under the treatment of medical men attached to the dispensaries for some time before their existence was notified to him, and sometimes his only sources of information were the weekly mortality returns. He considered that great inconvenience and possible danger to the general health of the city might be occasioned by this delay, and hoped that something might be done in future by which such delay might be prevented.

#### THE APPLICATION OF PENALTIES UNDER THE MEDICAL ACT.

MR. R. H. S. CARPENTER, Secretary of the Medical Alliance Association, has forwarded to us a copy of correspondence between himself and the President of the General Medical Council, including correspondence with the Receiver for the Metropolitan Police District, respecting the application of penalties obtained in cases of prosecution under the Medical Act. The manner in which the penalties in the Metropolitan District are appropriated on behalf of the Exchequer instead of being, as the Medical Act provides, paid to the Treasurer of the General Medical Council, has already been several times noticed in our pages, and has been the subject, on the part of the Medical Council, of resolutions and of communications with Government. The matter will, we learn from the correspondence, be again brought before the Executive Committee of the Council; and it is to be hoped that action will be taken to remove the anomalous condition under which, in the metropolitan district, the penalties recovered under the

Medical Act are diverted from their equitable destination. In the meantime, it is interesting to notice that, in the letter to the Receiver-General, Mr. Carpenter quotes some very high authorities—viz., Sir P. B. Maxwell, in his work on the *Interpretation of Statutes*; the Master of the Rolls, in the case of the Dean of Ely *versus* Bliss; and Chief Justice Lord Campbell, in the case of *Miller versus Rhind*—to show that (to use Lord Campbell's words) "without any express repeal, if a subsequent enactment is contrary to and inconsistent with a prior enactment, the prior enactment is repealed". Notwithstanding this, the Receiver, in his reply, entirely ignores these authorities, and falls back on the opinion of the solicitors to the police, under whose guidance he has acted.

#### RUSSIAN EPIDEMICS.

ACCORDING to the Russian press, an appeal has been made to the Government from Alexandropol for a grant of money to cleanse the town, on the ground that, owing to the passage of seventy thousand sick and wounded through the town since the war began, and the neglect of the local authorities to disinfect the place, the streets and the houses are filled with disease. The death-rate is 55 per 1,000, and nearly every house that has not been converted into an hospital for the army contains inhabitants stricken with typhus. At Tiflis, the operations of one branch of the Red Cross Society are entirely suspended, all the doctors being dead. It is expected in the Caucasus that a plague will break out in the spring. At Penza, small-pox and measles are rife. Near St. Petersburg, the black small-pox has broken out among the Turkish prisoners interned at Gatchina; and it is further stated that ten thousand sick and wounded are awaiting removal at Sistova. So many are suffering from typhus that it is proposed to have "typhus trains" to carry soldiers infected with that disease only.

#### HEREDITARY CONGENITAL DISLOCATION OF THE CRYSTALLINE LENS.

AT the meeting of the Medical Society of London on January 14th, Mr. Wordsworth exhibited six persons belonging to one family who are all affected by congenital displacement of both crystalline lenses. They consist of Mrs. H., her two sons, and their three children. A third son of Mrs. H. (now in New Zealand) was examined many years since, and his case described in the first volume of the *Royal London Ophthalmic Hospital Reports* by Mr. Dixon. In addition, Mrs. H. states that her own father, his youngest brother, and her grandfather, were all similarly affected. If this be so, there is a series of ten cases occurring in five successive generations. They all complain of being short-sighted; and, on close examination by oblique illumination, and when viewed by the ophthalmoscope, the crystalline lens in each eye is seen to be displaced, and its edge visible in the pupil. In distant vision, they look through that part of the pupil in which the crystalline lens is absent; and for near objects, through the crystalline itself. The family recognised the defect in all who are subject to it; and in those they considered exempt, the examination confirmed their opinion.

#### THE CONTAGIOUSNESS OF DIPHTHERIA.

SOME facts relating to the contagiousness of diphtheria are given in the recent Report of the State Board of Health of California, in speaking of an epidemic of diphtheria which occurred in April, 1876, in the Asylum for Orphans at Vallejo. During the period referred to, there were forty-three cases and ten deaths. The Board state that "one of the business men of Vallejo was called to Santa Rosa, Sonora County, to attend the funeral of some members of a family of relatives who had died from the scourge diphtheria. On returning to Vallejo, he and some of his family were taken down with the disease, and were attended by members of a family residing near the Home for Orphans. The children of the last-mentioned family were attending the school of the Orphans' Home at the time they were taken sick. Two of the family died, and soon after some of the Home inmates were taken sick with the same disease." During the prevalence of the epidemic, no suffi-

cient precaution was taken to isolate the sick, nor was attention apparently given to the fact of the contagiousness of the disease. The Board also give some interesting facts with regard to the transmission of diphtheria from point to point. A child just recovering from diphtheria went to visit a family at Dixon, wearing the same clothes as used during its illness. One of the children of this household was soon taken sick with the disease and died, there having been previously no diphtheria in the vicinity and no communication by the child with infected localities. Free intercourse with the sick was allowed, and the funeral of the deceased child was largely attended by other children, thereby causing an outbreak in the school near by, from which a large number of cases started. Not one person became ill who had not been exposed to direct contagion.

#### THE CHARITY ORGANISATION SOCIETY AND THE PROVIDENT SYSTEM.

At a meeting of the Council of the Charity Organisation Society on January 28th, Sir Charles Trevelyan moved the adoption of the following recommendations of the Medical Committee.

"1. That, in the opinion of this Committee, it is advisable to appoint a Subcommittee, with a suitable agent placed at its disposal, for the pose of extending and promoting provident dispensaries in the metropolis.

"2. That it is desirable that a separate fund be placed to the credit of this Committee for the purpose of carrying out these objects."

After briefly pointing out the advantages of the provident system of medical relief, as well as the growing public opinion in its favour, Sir Charles adverted to the special difficulties it has met with in the metropolis. The Council of the Society have always regarded it as a most important branch of charity organisation, and through their District Committees they have great facilities for pressing it upon the attention of the managers of medical charities all over London. The proposal was favourably received, and referred to the Administrative Committee for consideration. We are glad to observe that Mr. T. Holmes has accepted the chairmanship of the Medical Committee of the Charity Organisation Society, *vice* Sir Charles Trevelyan, who has resigned.

#### BRITISH MEDICAL BENEVOLENT FUND.

THE annual meeting of subscribers to this Fund was held on January 10th at Messrs. Churchill's, New Burlington Street, when the report of the Committee was presented, and the officers were chosen for the ensuing year. The hard times have pressed heavily on the resources of the Fund; for, not only has the number of applicants for relief been larger than hitherto, but there has also been a smaller amount of money wherewith to help them. In no year since the establishment of the Fund, in 1836, has so much been expended in giving immediate aid, £1,640 having, by the aid of a bank deposit, been distributed in the form of grants to needy members of the profession, their widows or their children. It has been doubted whether there really is such distress in the medical profession as can be relieved by small grants of money; but it is a fact, with which perhaps only those conversant with the working of this charity are familiar, that there are numbers of medical men or their relatives whom such help does preserve from abject poverty. There are persons, nearer to them than many may imagine, for whom a few pounds at once, or a few shillings in weekly doles, provide the only means of sustenance. Another branch of the Fund is that for giving annuities of from £10 to £25 to deserving members of the profession above sixty; but the number of applicants is so large, that it is rare for any one to obtain this boon before the age of seventy. The working expenses of the Fund are small, beyond those for postage and printing. The officers are all honorary, and the room, in which the Committee meets monthly, is very kindly lent by Messrs. Churchill. We venture, therefore, to urge the claims of this Fund upon the charity of every medical man. There are many, we believe, who do not give, because the existence of the Fund has been unknown to them; and we would ask them now, with these few facts before them, to do all they can, and to get others—their friends in the pro-

fession, and not less their friends in the laity—to help this really benevolent work. The Treasurer, Dr. Broadbent, 34, Seymour Street, Portman Square, or the Financial Secretary, Mr. Herbert W. Page, 28, New Cavendish Street, W., will gladly acknowledge any new subscriptions or donations which may be sent to them.

#### SMALL-POX AT HARWICH.

THE epidemic of small-pox at Harwich, we are informed, is much on the decline. Only four cases occurred last week. Of these, three only were admitted to the hospital. Thus there is reason to believe that the means taken for isolation have not been ineffectual. The death-rate was not lessened; but the greatest mortality took place amongst the patients admitted during the first week. It is further reported that some influential inhabitants of Harwich have petitioned the Local Government Board to institute an inquiry into the cause of the outbreak of small-pox. At Dovercourt, the people formed a local committee and stamped out seven cases, and they are now entirely free. No deaths have taken place among those recently re-vaccinated. A number of young people have died. The nurses belonging to the St. Alban's Diocesan Nursing Association are doing their duties in the temporary hospital admirably, in the face of considerable difficulties.

#### HEALTH OF FOREIGN CITIES.

THE Registrar-General states that a summary of the weekly returns with which he is favoured by various local authorities abroad, shows that the average annual death-rate during the fourth quarter of the year 1877 in thirty Indian and foreign cities, was 28.4 per 1000, against 22.8 in twenty of the largest English towns. The population of these thirty foreign cities is estimated at about twelve and a half millions of persons. In these cities, the lowest death-rates were 16.5 and 17.7 in Philadelphia and Christiania; whereas the rates ranged upwards in the other towns to 44.9 in Bombay, 45.7 in Alexandria, and 97.3 in Madras. The mortality in Madras, though it showed a considerable decline from that in the preceding quarter, still continued high; the 9,636 deaths during last quarter included 438 from small-pox, and 381 from cholera. In Calcutta 347, and in Bombay 127 deaths were referred to cholera. In St. Petersburg, 544 deaths resulted from fever; equal to an annual rate of 3.26 per 1000. In Paris, the deaths from typhoid fever were 327, equal to an annual rate of 0.66 per 1000; whereas in London the rate from this disease did not exceed 0.39. In Berlin and Philadelphia, typhoid fever was especially fatal. Small-pox showed more or less prevalence in Madras, St. Petersburg, Vienna, and Trieste. Scarlet fever caused 331 deaths in Berlin, against 154 and 269 in the two preceding quarters; this disease also prevailed in Stockholm, Dresden, and in the American cities. To diphtheria, 347 deaths were referred in Paris, 306 in Berlin, 337 in New York, and 193 in Brooklyn; showing in each of those towns an increase upon the numbers returned during the preceding quarter.

#### THE LIVERPOOL SAILORS' HOME.

AT the annual meeting of this Institution held on Monday last, the chairman alluded to the great benefits which had resulted from the establishment of the Seamen's Dispensary. This year's report states that the dispensary was opened on February 26th, 1877, to the seamen of all nations, whether boarders in the Home or not. Mr. F. W. Lowndes and Dr. A. E. Bernard, the medical gentlemen who in the first instance volunteered their services, and to whose energy and perseverance is largely due the success of the institution, reported that, since the opening of the dispensary, 847 patients had applied for advice, and there had been 2,363 attendances. The patients had all been supplied at the dispensary with medicines and other requisites, at the uniform charge of one shilling for each attendance. Patients proceeding to sea were provided with extra medicine when required. The result of the first year's trial showed very conclusively that the dispensary would not only be self-supporting, but that in the forthcoming year a substantial surplus may be expected. The dispensary

had been the means of supplying a great want. The medical officers had in numerous instances received the most gratifying acknowledgments from different patients of the value of this addition to the many other institutions provided for their benefit. They greatly appreciated being able to obtain medical advice and medicine for so moderate a sum, and in such convenient proximity to the shipping and other offices. They were also sensible of the protection which the dispensary secured them from the extortions of the many self-styled "doctors" to be found in the vicinity of the Sailors' Home. Many patients, after having been cured, had returned with shipmates, while many others had heard of the dispensary in distant seaports from former patients. A detailed report of the results of this valuable institution is promised in a short time.

#### REGISTRATION OF DISEASE.

THE Boston City Board of Health has lately issued a circular which will be interesting to our readers in relation to a matter much discussed now, and which will probably be the subject of legislation. We give the following extract:

"Whereas diphtheria is a disease contagious and dangerous to the public health, and whereas it now exists in the city of Boston; therefore the Board of Health issues the following notice: That on and after January 1st, 1878, the following provisions of Chapter 26 of the General Statutes will be strictly enforced.

"Sect. 47. When a householder knows that a person within his family is taken sick of...any...disease dangerous to the public health, he shall immediately give notice thereof to the...board of health of the town in which he dwells. If he refuse or neglect to give such notice, he shall forfeit a sum not exceeding one hundred dollars.

"Sect. 48. When a physician knows that any person whom he is called to visit is infected with...any disease dangerous to the public health, he shall immediately give notice thereof to the...board of health of the town: and if he refuses or neglects to give such notice, he shall forfeit for each offence a sum not less than fifty nor more than one hundred dollars."

#### SCOTLAND.

THERE is at present a considerable epidemic of measles in Edinburgh. Last week, thirteen deaths were attributed to this disease. The only other deaths from any zymotic complaint were five from whooping-cough and one from fever.

THE convener of the county of Bute, Mr. A. B. Stewart, has undertaken at his own expense to erect a considerable addition to the hospital at Rathesay, to be used for the purposes of a general hospital. At present, there is only room for patients suffering from contagious diseases.

A NOTE of the rainfall at Glasgow for the past three years has just been published by the Superintendent of the Glasgow Parks. The table for 1877 shows a total fall of 48.03 inches. The greatest fall was in January (9.39 inches); and the least in September, when only 1.50 inches fell. The rainfall of 1877 was about one-fourth in excess of the the two preceding years; the dry days one-third less; while the mean temperature was almost equal.

THE Edinburgh Association for Incurables, an institution which has been in existence only for a few years, has just issued its annual report. The present building in Salisbury Place having been found too small to meet their requirements, the two adjoining houses have been acquired, and will be available at or before Whit Sunday, when the managers expect to be able to commence building operations immediately. They trust that part at least of their new hospital will be ready for occupation next year. During the year, the Committee have received a legacy from Mr. Ross amounting to £1,360. They have also received intimation of a legacy of £1,000 to be paid "when the hospital is erected, towards the expense of the building", after the death of the testator's widow. On January 1st, 1877, there were in

the hospital eleven males and twelve females. The special thanks of the Association were given to the trustees of the late Mr. J. A. Longmore for their promised grant of £10,000 for the building of the new hospital.

#### HEALTH OF GLASGOW.

IN his report of the health of the city of Glasgow for the fortnight ending January 26th, Dr. Russell mentions the following facts of interest. There was, he says, one case of small-pox registered, the origin of which was interesting. In his report for the fortnight ending December 1st, he had stated that two sailors belonging to the ship *Roseneath*, which left Montreal on October 27th, and on board of which small-pox had appeared, had been removed to hospital. The woman with whom one of these men lodged declined to accept of revaccination. She sickened on December 23rd, and died on the 29th of what seemed to be typhus fever; but her husband, who works in Millwall, London, as a shipwright, and who came down on his wife's decease, was seized with small-pox on his return, and was now in Highgate Hospital; and the case now reported in Glasgow was a next-door neighbour, who attended to the poor woman in her sickness. He had now no doubt that she died from malignant small-pox. The number of cases of fever registered was 84; viz., 80 enteric fever, 3 typhus, and 1 undefined. The number of cases of enteric fever among the persons known to be supplied with infected milk had now increased to 72 within Glasgow; but no fresh cases had arisen since the week ending January 12th. The persons suffering from enteric fever at the present time were distributed through the city thus: Central District, 4; Eastern District, 23; Northern, 17; and Western, 44. A dairy-owner, who sent a large quantity of milk into the city daily, had made a special request that his premises might be examined by a competent authority; and he might also add that an officer was going the rounds of a number of dairies, endeavouring, if possible, to trace the outbreak of fever in the east end.

#### REPRESSION OF BABY-FARMING.

AT the Edinburgh Police Court last week, a man and his wife were charged with an offence against the Infant Life Protection Act, second section, in that, between the 27th of November last and the 25th of January, they unlawfully retained or received for hire two infants under the age of one year, not being twins, for the purpose of nursing or maintaining them apart from their parents in their house aforesaid, which was not registered under the third section of the said Act, whereby they were each liable to be imprisoned for a period not exceeding six months, with or without hard labour, or to pay a fine of five pounds. An agent for the accused explained that they were very respectable people, and had acted in ignorance of the Act. Under these circumstances, a fine of five shillings only was imposed.

#### ADULTERATION IN GLASGOW.

THE Glasgow City Analysts, in a report on the articles examined by them during the past quarter, say that the samples of milk, flour, bread, oatmeal, and wine were genuine. All the coffees were adulterated with chicory, the proportion of which varied from one-tenth to two-thirds of the entire weight. Of the samples of arrowroot, three were genuine, two consisted entirely of tapioca-flour, and one of potato-starch and Indian-corn starch. The malt liquors consisted of bitter beer, sweet ale, and porter. All were of good strength and in fair condition; but, of the seven samples, three were found to contain an excessive quantity of salt.

## IRELAND.

#### LIMERICK UNION.

AT a meeting of the guardians, held on the 30th ultimo, to appoint a medical officer to the Workhouse in the room of Dr. O'Kelly, resigned, a resolution was adopted that the salary should be reduced from £200,

as advertised, to £150 *per annum* with rations and apartments. Dr. McAuliffe refused to accept the post at the reduced salary and withdrew his candidature, being allowed travelling expenses. There were three candidates at the reduced remuneration, Dr. Russell being elected by a majority of votes.

#### CLONASLEE DISPENSARY.

LAST week, the election of a medical officer for the Clonaslee District took place, and caused considerable excitement owing to the interest shown in the appointment. There were two candidates, Dr. Neale and Dr. McKenna, the former being elected by a majority of one. One of Dr. McKenna's supporters urged his election because he was a Roman Catholic; but Dr. Neale's proposer very properly pointed out that the question of a candidate's religion should not be alluded to, and that being a member of any particular creed could not constitute a man a good doctor, unless he could rely on his own abilities.

#### THE CORK STREET FEVER HOSPITAL.

WE announced last week that Dr. Grimshaw's term of office, as physician to this hospital, had expired. The governors of the hospital have, we are glad to learn, shown their appreciation of Dr. Grimshaw's services during the fourteen years he has been in connection with it by appointing him Consulting Physician. This graceful compliment is more highly esteemed, inasmuch as it has never been conferred before, we believe, upon any of Dr. Grimshaw's predecessors.

#### HEALTH OF DUBLIN: ANNUAL REPORT.

DURING the past year, there were registered in the Dublin Registration District 9,325 births, being equal to a ratio of 1 in 34, or 30 per 1,000 of the population; and 8,795 deaths, or 28.0 per 1,000. The deaths from zymotic diseases numbered 1,528, or 48.6 in every 10,000 of the population, exceeding the mortality from these causes in either of the two preceding years, but 218 deaths under the annual average for the ten years 1867-76. Nearly one-third of the total mortality from zymotic diseases was produced by measles and its complications, the deaths from which amounted to 461. Small-pox caused 38 deaths; fever, 280; diphtheria, 23; erysipelas, 29; whooping-cough, 106; croup, 101; diarrhoea, 156; and scarlet fever, 122, the smallest number in any year since 1866, and only one-third of the average annual number for the ten years 1867-76. The deaths from convulsions numbered 629, being exclusively those of children, and, with nine exceptions, were amongst those under five years of age. Bronchitis proved fatal in 1,388 cases; pneumonia, 310; pleurisy, 18; and lung-disease, unspecified, in 147. Diseases of the heart and organs of the circulation caused 452 deaths; paralysis, 182; apoplexy, 123; epilepsy, 38; brain-disease, unspecified, 157; Bright's disease, 50; and kidney-disease, unspecified, 79. Deaths from "constitutional diseases" numbered 1,720, being about 5 per cent. over the average for the previous ten years; they comprised 1,030 from phthisis, 174 from hydrocephalus, 172 from mesenteric disease, 61 from scrofula, 161 from cancer, 10 from gout, etc.

#### ULSTER EYE, EAR, AND THROAT HOSPITAL.

THE seventh annual meeting of the Committee and subscribers of the hospital was held, on the 29th ultimo, at Belfast. During the past year, 3,041 cases were treated in the institution, 155 of whom were intern patients. The expenditure was somewhat in excess of the annual income; and the Committee regret that a debt of £200 still remains, and appeal to the subscribers and the public to help them to clear off this debt, which so materially hinders the usefulness of the institution. With a view of rendering the hospital available for all classes of the community, the Committee have framed rules regulating the mode and terms of such admission, which may be summarised as follows. Poor patients may be admitted to the general ward by a subcommittee, or by the acting surgeon, free of charge. Any suitable case will be admitted on payment by the patient, or by any other person, at the rate of ten

shillings a week. Private patients, under the care of the acting surgeon, may be admitted to hospital on payment of fifteen or thirty shillings a week, according to the ward selected; the acting surgeon to be at liberty to charge his fees to such private patients the same as if he rendered them his services in their own homes. The Committee have forwarded copies of these rules to boards of guardians, and to persons interesting themselves in the welfare of individual patients, and in many instances there has been a satisfactory response.

#### THE LATE DR. CHURCHILL.

THE funeral of this distinguished and much respected obstetrician took place at Stewart-town, county Tyrone, on Monday last. By the wish of the family, the ceremonial was strictly private. At the usual stated monthly meeting of the King and Queen's College of Physicians, on the 1st instant, it was resolved to adjourn the meeting to that day week, in consequence of the announcement of Dr. Churchill's death. The Registrar was likewise directed to communicate to Dr. Churchill's family the feelings of regret with which the College had received the sad intelligence, and the sympathy it felt towards them in their bereavement; and also to inform them that, during the long period of Dr. Churchill's association with the College, as Fellow and President, he had not only secured the good opinion of every one connected with it, but had rendered it the most valuable services by his learned labours in many other ways, which had redounded to the credit and advantage of the body. A resolution of condolence with the family of the late Dr. Stokes, a Fellow and ex-President of the College, was also passed at the same meeting, the first since his death.—The meeting of the Pathological Society of Dublin, last Saturday, was also adjourned in consequence of Dr. Churchill's death.

#### SCIENTIFIC LECTURES.

THE first lecture of this year's course of annual scientific lectures, in the King and Queen's College of Physicians, was delivered, on Monday last, by Dr. Walter Smith. We have already published the names of the three lecturers selected by the College and the subject of their lectures. Dr. Smith's first lecture dealt with the physical basis of electro-therapeutics. After a brief historical sketch, and the explanation of some fundamental physical conceptions, the lecturer proceeded to treat of the forms of electric currents utilised in medicine, which he arranged as follows. 1. *Galvanic (Voltaic) Currents*: 1. Continuous; 2. Interrupted: (a) direction uniform; (b) direction alternating. II. *Induced (Faradic) Currents*: 3. Electro-magnetic; (a) extra-current of primary coil; (b) alternating currents of secondary coil; 4. Magneto-electric Currents. Each form of current was illustrated by diagrams, and the two varieties of interrupted galvanic current were experimentally shown. With the aid of Sir W. Thomson's reflecting galvanometer, the alternating currents of the secondary coil and magneto-electric currents were demonstrated, and the greater physiological effect of the opening current was exemplified on the muscles of the forearm. With a current of suitable intensity, no contraction was produced on completing the circuit; but, on breaking contact, a marked contraction was obtained. The lecturer next spoke of electro-medical apparatus; and recommended for general adoption, either the Leclanché battery, or the recent modification of it proposed by Clamond, in which peroxide of iron is substituted for the peroxide of manganese. From seven years' experience of the Leclanché battery, Dr. Smith believes that it answers every demand that can reasonably be made upon it, even although, being a single fluid combination, it cannot give either a constant electro-motive force or a constant resistance. Of induction machines, those furnished with coils, worked by a zinc-carbon cell in the bichromate of potash solution, were recommended as portable, easy to manage, and thoroughly satisfactory. For electrodes, carbon or metal terminals are more cleanly and convenient than the ordinary cup sponge-holders, which offer greater resistance and may be entirely dispensed with. A simple hand instrument, by which a galvanic current can either be interrupted by moving a spring or commutated, was shown and its action demonstrated

on a galvanometer. Some such appliance should be supplied with every galvanic battery intended for medical use. The latter part of the lecture was devoted to an exposition of the laws of the transmission, diffusion, and localisation of electric currents in the human body. The cases were considered successively of the propagation of electricity along linear conductors, and through conductors of three dimensions, homogeneous and heterogeneous; and the complex nature of the problem in reference to the human body was pointed out. It was next explained how although, strictly speaking, it is impossible to absolutely localise an electric current in any part of the body, a relative localisation of a current can be effected. The different factors that influence the localisation of currents were explained and illustrated. With the aid of diagrams, it was shown how the density of the current is altered by modifying the dimensions of the electrodes; how the distribution of the electric curves can be controlled by varying the distance which separates the two electrodes; and how enormously the resistance of the skin varies, according as dry or moist electrodes are employed. Dr. W. Smith's second lecture will be delivered next Monday.

#### HOUSE OF INDUSTRY HOSPITALS.

HIS Grace the Duke of Marlborough, K.G., Lord-Lieutenant of Ireland, paid an official visit to these hospitals yesterday week. The House of Industry Hospitals comprise three distinct and separate buildings, viz., Richmond Surgical Hospital, the Whitworth Medical Hospital, and the Hardwicke Fever Hospital, as well as a large general and ophthalmic dispensary building. These hospitals, which together furnish accommodation for over 320 beds, are under the management of a board, the members of which are appointed by the Government, and receive for their support an annual Government grant of about £7,500. It is understood that the Richmond Hospital especially is much in need of repairs and alterations; and that its immediate surroundings—cow-houses, etc.—are very objectionable from a hygienic point of view. The visit of the Lord-Lieutenant will, it is to be hoped, induce the Government to make the required improvements at an early date.

#### REMOVAL OF SMALL-POX PATIENTS TO AN HOSPITAL.

THE parents of a small-pox patient, living in the vicinity of Dublin, recently refused to allow the removal of their son to hospital when ordered there by his medical attendant. A warrant, under the 54th section of the Public Health Act, was consequently directed to the police-constable of the district for the removal of the patient. On proceeding to execute it, the patient's father stood in the room with a large stone-hammer in his hand, and declared that any man who approached to take away his son would have his brains knocked out! The constable evidently thought discretion the better part of valour, for he took his departure without even arresting the father, which we believe the same Act gives authority for doing—the man having wilfully obstructed the execution of the order. Another small-pox patient in the same district, whose parents also refused to allow her to be moved to hospital, has since died. Such conduct on the part of these peasantry is doubtless, in great measure, due to ignorance of both the laws of the land and of sanitary science; and we think the guardians of the union in which these cases occurred have shown their sense by having explanatory posters printed and published throughout the union, and by prosecuting the minatory father.

#### PUBLIC HEALTH IN IRELAND.

THE Government Bill "to consolidate and amend the Acts relating to Public Health in Ireland" has been printed. It consists of 292 clauses. A memorandum prefixed to the Bill states that its objects are "to consolidate into one Act the various provisions with respect to sanitary matters and burial grounds of the several Acts—no fewer than twenty in number—now in force in Ireland, and to amend the same where such amendment is required". The memorandum also gives a full summary of the provisions of the Bill.

## THE BRITISH MEDICAL ASSOCIATION IN IRELAND.

THE first annual meeting of the Dublin Branch of the British Medical Association was held on Thursday, January 31st, 1878; Dr. ALFRED HUDSON, Physician in Ordinary to the Queen in Ireland, and President of the Branch, in the chair. There was a very large and influential attendance of members of the Branch and of the profession generally. Among those present were: Dr. Eason Wilkinson, President of the British Medical Association (Manchester); Mr. Ernest Hart, Editor of the BRITISH MEDICAL JOURNAL (London); Dr. James Cuming, President of the North of Ireland Branch (Belfast); Dr. Curtis, President of the South of Ireland Branch (Cork); Dr. R. M'Donnell, President of the Royal College of Surgeons of Ireland; Dr. Samuel Gordon, President of the King and Queen's College of Physicians; Mr. Porter, Surgeon to the Queen in Ireland; Dr. T. Darby, President of the Irish Medical Association (Bray); Dr. P. C. Smyly, Vice-President of the Royal College of Surgeons of Ireland; Dr. Little, Vice-President of the King and Queen's College of Physicians; Dr. W. Adams; Dr. L. Atthill; Dr. Bell; Dr. E. H. Bennett; Dr. S. L. Bigger; Dr. Blood; Dr. Boyce (Stillorgan); Dr. Brunker (Dundalk); Dr. F. E. Clarke (Drogheda); Dr. E. Collins; Mr. T. Collins; Mr. D. Corbett; Dr. Doyle; Dr. J. F. Duncan; Mr. R. W. Egan; Dr. M. Eustace; Dr. J. M. Finny; Dr. A. W. Foot; Mr. H. J. K. Gogarty; Dr. T. W. Grimshaw; Dr. Hamilton; Dr. R. J. Harvey; Rev. Dr. Haughton; Dr. Hayden; Dr. Head; Mr. R. T. Hearn; Dr. G. Johnston; Surgeon-Major J. Johnston; Dr. Macnaughton Jones (Cork); Dr. J. B. Kelly (Drogheda); Dr. H. Kennedy; Dr. J. Lalor; Dr. Macan; Dr. McClintock; Dr. MacSwiney; Dr. Mapother; Dr. T. P. Mason; Dr. H. Minchin; Dr. Moore (Belfast); Dr. J. W. Moore; Dr. Murray (Ashfield Beauparc); Dr. E. S. O'Grady; Dr. L. H. Ormsby; Dr. A. Patton (Finglas); Mr. W. B. Pearsall; Mr. E. Peele; Dr. J. F. Pollock (Blackrock); Dr. F. T. Porter; Dr. G. D. Powell; Dr. T. Purcell; Dr. J. M. Purser; Dr. C. H. Robinson; Dr. E. B. Sinclair; Mr. A. O. Speedy; Dr. W. T. Soker; Dr. W. Stokes; Mr. H. R. Swanzy; Dr. Glascott Symes (Kingstown); Dr. W. Thomson; Dr. Truell (Clonmannon).

*Report of Council.*—The minutes of the previous special general meeting having been read and confirmed, the report of the Council was read by the Honorary Secretary, Dr. DUFFEY. It was published at page 167 of last week's JOURNAL.

Dr. JAMES LITTLE (Vice-President of the King and Queen's College of Physicians), in moving the reception and adoption of the report, said: I think we may fairly congratulate the Council on the successful meeting which is now assembled to inaugurate this Branch of the British Medical Association. When the project was first started—I had almost said when Dr. Duffey first started it—many persons questioned the utility of the measure, and wanted to know the object to be attained by the members of the profession thus uniting together. I think the numbers here to-day attest that Dr. Duffey has succeeded in convincing the members of the profession in this city that we do well to unite together as a Branch of this great Association, and to put ourselves into active physiological relation with the parent Association in England. There can be no doubt that we will derive very great advantages from being thus actively associated with the British Medical Association, which is probably the most powerful medical organisation in the world, and it will insure to us the cordial support of that organisation. This Branch will also serve to keep alive feelings of goodwill and an interchange of that friendly intercourse which is so desirable among the members of the profession; though I am glad to say that this is a direction in which the aid of the Branch was least needed here, for there is probably no other city in Europe where the same number of medical men are engaged in friendly rivalry, and where the same cordial terms subsist between the various members of the profession. [*Hear, hear.*] I think we may also take it that the British Medical Association will lose nothing, but gain a great deal, by having the Branch thoroughly organised and added to its other branches. In many respects, the Dublin Branch will be an exceptional one. It differs in many respects from the provincial Branches, and also from the Scotch Branches. In the first place, it is formed in a capital city; and, in the next place, I do not suppose there is in England a city which could afford a larger number of members than does Dublin and the small towns surrounding it. In such an Association as the British Medical Association, numbers count for a good deal. With the exception of London, this is, perhaps, the largest medical school in the three kingdoms; and I cannot help feeling that the younger members of the profession, in coming forward and joining this Branch, will have the opportunity of getting their ideas associated in this British Medical

Association; and this Society will prove to be a good feeder for the other Branches in England. It has always appeared to me that organisations such as these are of the highest value, and anyone who reads the JOURNAL in England must be aware of the fact that not only are matters which concern the material interests of the members of the profession attended to by this Association, but there is a large amount of scientific work done at the meetings. If an association contented itself with carrying out those measures which would secure proper pay and provision for the various members of the public service—if an association concerned itself only with such matters—the public would consider it very little better than a trade organisation for the protection of their own interests. But, when we find a vast amount of scientific work is done, that the various members vie with one another in bringing their contributions to the store of professional knowledge, all that can be said by the public is that such an association is concerned as much for the protection of public as professional interests. I think these Branches will tend to establish most firmly public and professional support. This is a Branch that will give us the opportunity of sending representative men to England and of doing honour to those among us who deserve it. We will not send men who are not likely to deserve the honour by their professional attainments, blameless professional life, and eminent public worth. [*Applause.*] I have much pleasure in offering my congratulations to the Council and to the Honorary Secretary on the importance and truly representative character of this meeting, and beg to move that the report now read be adopted. [*Applause.*]

Mr. P. C. SMYLY (Vice-President of the Royal College of Surgeons): I have much pleasure in seconding the motion; and I thought when I heard the report read that it was so exhaustive that nothing could be added to it. But I think we are all indebted to the Vice-President of the College of Physicians for the way in which he has spoken. [*Hear, hear.*] The report is most satisfactory; and I think we may be very well pleased with the promise of success that this Branch has now before it. There certainly is a very good representation in this room not only of the members of the profession in Dublin, but I see many worthy faces from distant parts of the country who have come to support us here to-day. Dublin certainly might do a great deal by itself; but the profession in Dublin feel a debt of gratitude to the country practitioners who come from the most distant parts to aid us with their advice and assistance on all occasions, and I think that an Association supported by such men as I see around me to-day may very well look forward to a brilliant future. [*Applause.*] I have great pleasure in seconding the adoption of the report of the Council.

The motion was passed unanimously.

*New Members.*—The HONORARY SECRETARY read a list of twenty-two gentlemen who had been duly proposed and seconded, and who were desirous of becoming members of the Association; and, on the proposal of Dr. DUFFEY, seconded by Dr. MCCLINTOCK, they were elected. In addition, several members of the Association were elected members of the Branch.

*President's Address.*—The PRESIDENT read an address, which appears at page 186.

*The New President.*—The officers and Council for the ensuing year, whose names were given at page 167 of last week's JOURNAL, having been elected, the President vacated his chair.

Mr. G. H. PORTER (Surgeon in Ordinary to the Queen in Ireland), the new President, then took the chair amid applause. He said: Gentlemen,—I thank you most sincerely for the great honour you have conferred upon me to-day, partly by your kindness, and partly by the good rule—for I do believe it to be a good rule—that, in rotation, a physician and a surgeon should occupy your presidential chair. The honour you have conferred upon me is greatly enhanced by the fact that I succeed so distinguished a physician as my friend and colleague Dr. Hudson. I promise you this, that during my year of office I shall do everything in my power to raise the status of this your new Branch [*applause*], so that when I shall vacate the chair the Branch may be found, or I trust it may be found, in as wholesome a condition as it promises to be to-day. [*Renewed applause.*]

*Vote of Thanks.*—Dr. GORDON (President of the King and Queen's College of Physicians): It is a source of great gratification to me, sir, that this resolution has been put into my hands—a resolution conveying the thanks of this Branch to our ex-President. His reign over us has been but short; but, although short in time, it has been pregnant with a great deal of advantage. He has had the trouble of originating this Branch as Chairman, and he has presided over our meetings with the usual courtesy and energy for which he is so famous, and, lastly, he has crowned his brief period of office to-day with the admirable address to which we have just listened—an address that will be long remembered for all the different topics that he has managed to introduce into it

so very short a time, and for the ability with which it has been delivered. I have the greatest pleasure in moving :

"That the warm thanks of this Branch be given to our ex-President, Dr. Hudson, for his admirable address, as well as for the ability with which he has presided over the Branch during the first year of its existence, and for the interest he has taken in its formation." [*Applause.*]

Dr. MCCLINTOCK : I rise with feelings of very great pleasure and satisfaction to second the motion which has been put to the meeting by the President of the College. I need hardly say that I concur to the fullest extent in every word of praise and commendation that he has said as regards the outgoing President during his term of office, and also as to the ability that he has displayed in his address. Like his other contributions to medicine, though not many—not at all so many as we would wish—it yet bears unmistakable evidence of thought and reflection, and of a richly cultivated mind and understanding. I need say no more than that I am sure all the members present will heartily and entirely acquiesce in the reception of this proposition ; and I think it would be hardly necessary to put it formally to the meeting, for I have very little doubt that a resolution of this kind will be carried by acclamation. [*Applause.*]

The resolution was then passed by acclamation.

Dr. HUDSON : I beg to return my warm thanks to the kind friends who have spoken in too flattering a way of me, and to express my indebtedness to them for the patience with which they listened to me. [*Applause.*]

The proceedings of the annual meeting then terminated.

*The Dinner.*—In the evening, a large number of members and their guests sat down to dinner in the "Hall of the Statues" of the College of Physicians. Covers were laid for eighty. The chair was occupied by Mr. George Porter, Surgeon-in-Ordinary to the Queen, and President of the Branch. To the right of the chairman were—Dr. Wilkinson, Manchester, President of the British Medical Association ; Dr. Gordon, President of the King and Queen's College of Physicians ; and Dr. Curtis, Cork, President of the South of Ireland Branch. To his left were—Dr. Darby, Bray, President of the Irish Medical Association ; Dr. Robert McDonnell, President of the Royal College of Surgeons ; Mr. Ernest Hart, London, Editor of the BRITISH MEDICAL JOURNAL ; and Rev. Professor Haughton. The guests also included Sir George Owens ; Dr. Cuning, Belfast, President of the North of Ireland Branch ; Dr. Moore, Belfast ; Dr. Macnaughton Jones, Cork ; Dr. Brunker, Dundalk ; Mr. Drew, R.H.A. ; Dr. Shaw, Trinity College ; Dr. Patton, and Dr. Jacob. After the usual loyal toasts were proposed,

The CHAIRMAN said: Gentlemen, I have now to ask you to drink what we may truly regard as the toast of the evening, namely, "The Health of the British Medical Association". With it I couple the name of its president, our distinguished guest, Dr. Wilkinson. My first and most pleasing duty is to thank him for his great kindness in coming over to attend our meeting of to-day, and in joining us at this festive board. The British Medical Association requires no eulogy from me. You all know the good work it has done since the day of its foundation. Not only has it extended in every way the knowledge of medicine and surgery, but it has always nobly upheld the rights of the medical profession whenever these have been assailed. I therefore ask you to drink "The British Medical Association, and Dr. Wilkinson".

The toast was drunk with enthusiasm.

Dr. WILKINSON, in returning thanks, said: I have much pleasure and satisfaction in being here to-day, at the first meeting of your Branch, which, I am informed, already numbers more than a hundred members. It is now many years since I joined the Lancashire and Cheshire Branch of this Association, which was then called the Provincial Medical and Surgical Association. At that time our Branch did not claim many more members than you do now. At the present time our Branch is one of the largest of the British Medical Association. How was this accomplished? Mainly through the energetic character of our founder, Sir Charles Hastings, who stimulated the local secretaries to increase their members, and to strive to enlist in the ranks of this Association every medical man in the kingdom. Secondly, through the zeal and activity of our secretaries, who spared no pains to accomplish their leader's object. What they have done, yours may do. Thirdly, through the means of the JOURNAL, and the influence which it has exercised as a means of scientific communication, and in promoting the other objects of the Association. In a scientific and social point of view the scheme has brought together men who were isolated from their fellow-labourers, and has enabled them to exchange ideas, and thus to stimulate each other to advance our

noble profession, and to increase our means of doing good to those entrusted to our charge. Further, in a social point of view, it has enlarged our way of regarding men, and has helped to rub off many of the asperities with which we regarded one another. It tends to show that we are dependent one on the other, and I can certainly see a kindlier feeling pervading our ranks than existed formerly. When we remember that our Association now numbers nearly 8,000 members, I think we may fairly say that it is making a steady advance towards the realisation of its founder's hopes. [*Applause.*] Dr. Wilkinson then said—The formation of the Dublin Branch of the British Medical Association is a source of sincere congratulation to the Association at large. It forms one more link in the bond which the founders of the Association desired, that it should unite the profession in the three kingdoms in the bonds of friendship, sympathy, conjoint scientific action, and moral influence in promoting the common interests of humanity, science, and medicine, which are identical in all the three kingdoms. You have here a valuable local Association—the Irish Medical Association—of which I am happy to see the President present to-night. [*Applause.*] We desire the sympathy and good will of that Association ; we hope to see it flourish. It has peculiar local advantages and national usefulness. We tender to it our aid in all its useful purposes, and we are delighted to see that it joins the other great medical institutions of Ireland, in extending the wish which I now propose to you in the form of a toast—"Prosperity to the Dublin Branch of the British Medical Association, coupled with the name of its respected President, Mr. Porter," whose reputation and character stand so high as to need no encomium from me. [*Applause.*]

The toast was drunk in an enthusiastic manner.

The CHAIRMAN said : Dr. Wilkinson, I am deeply indebted to you for the kind manner in which you have proposed the toast of the Dublin Branch of the British Medical Association, and mentioned my name in connection with it ; and, gentlemen, I thank you most heartily for the warm manner in which you have received the toast. I am not going to inflict a speech upon you. I assure you with sincerity that I would rather perform a capital operation than make a speech. [*Hear, hear, and laughter.*] At the same time I must on your behalf, as well as on my own, express to Dr. Wilkinson our warm thanks for the manner in which he proposed the toast which has just been drunk. I have to thank you also for placing me in the high and honourable position of being your President ; and I trust that I shall be fortunate enough to merit in every way the confidence which you have placed in me. I confess that it was for a long time a matter of reproach to us in Dublin that we had no Branch here of the British Medical Association. That reproach has been to-day happily removed. I can say very little for the Branch at present ; all we can do is to hope that it will have a bright future. [*Applause.*] I will now ask you to drink a toast which, I may say, is nearer home than any of the others. It is the Irish Medical Association ; and I couple with the toast the name of our old and valued friend Dr. Darby. [*Applause.*] His presence here to-night is a proof that there is no antagonistic feeling between the two associations. [*Hear, hear.*] The objects of both are in many respects the same. The Irish Medical Association is perhaps more exclusively a protective society. You all know that it has done good work. [*Applause.*] When attempts have been made on many occasions to crush our professional brethren, that Association has manfully fought their battles. I therefore call upon you to drink with enthusiasm "The Irish Medical Association and Dr. Darby". [*Applause.*]

The toast was most heartily received.

Dr. DARBY, on rising to respond, was received with warm applause. He said : Gentlemen, it has been my good fortune on so many occasions to return thanks for the toast of the Irish Medical Association, that anything that I can say now will be merely repeating myself. I thank you all very warmly for the manner in which you have received the toast. When the charge of the Medical Charities of Ireland was undertaken by the local bodies constituted under the poor law, the Irish Medical Association at once became a necessity ; and I would say that now there is no country in which medical charities are so well administered as they are in this. They afford most excellent, efficient, and valuable relief to the sick poor. The medical men who first administered that relief were placed in a very novel and difficult position, being overworked and under-paid. Undoubtedly at the time of the change in the law it was necessary to form an association in Dublin for the protection of medical men living in remote districts. The Irish Medical Association is now an important national institution, and I think we owe a debt of gratitude to the late Dr. Arthur Jacob, who laid the foundation of the Association, and to his son for the manner in which he has promoted the interests of the Poor-law medical officers in this country. [*Applause.*]

The CHAIRMAN : Gentlemen, the next toast on my list is one that I am

sure you will feel very great pleasure in having brought before you. Before mentioning it, I feel bound to say that I think we are very much indebted to our Honorary Secretary, Dr. Duffey [*Applause*], not alone for the formation of this Branch, in which, without offending any other gentleman, I think I may say he took a most active part, but also for the manner in which he has arranged the list of toasts now in my hand. The toast I am now about to give you is the health of the College of Physicians and the College of Surgeons in Ireland. It gives me a great deal of pleasure personally to propose this toast, because I have always thought, and think still, that the closer those two colleges are cemented together the better. [*Applause*.] No higher qualifications can be held by any man than the licences of those two colleges. We are indebted to the College of Physicians for the great privilege of having been able to dine in this beautiful hall to-night, as well as for that of holding our meeting here to-day. [*Hear, hear*.] The College of Physicians in Ireland has always been foremost in its efforts to aid the profession in every way. I beg to couple with the toast the names of the respected Presidents of those two colleges, Dr. Gordon and Dr. Robert McDonnell. [*Hear, hear*.] With respect to the College of Surgeons, it would ill befit my purpose to say much; still I cannot help making one or two remarks. I have been connected with it from my earliest days, and I believe that as a great national institution the College of Surgeons of Ireland has done its duty well, and has successfully endeavoured to send out on the great platform of life highly educated surgeons. I believe I may say, without fear of contradiction, that wherever surgery is practised, whether in some remote nook in distant lands, or on the field of battle, our licentiates have manfully and courageously upheld the prestige of Irish surgery. I give you, therefore, "The College of Physicians and the College of Surgeons, coupled with the names of Dr. Gordon and Dr. Robert McDonnell".

The toasts were received with acclamations.

Dr. GORDON, President of the College of Physicians, said: On the part of the College of Physicians, I return you my most hearty thanks for the way in which you have received this toast. I can only say on the part of the College of Physicians that, individually and collectively, nothing gives them greater pleasure than to assist in every way in their power in any effort on the part of any branch of the profession to forward views interesting to the profession or to the public at large. [*Applause*.] How much more, then, do they feel it to be their pleasure and their duty to assist in promoting the efforts and the objects of such a society as I see collected in these halls to-night, to whom, on the part of the College of Physicians, I give a most hearty welcome. [*Applause*.] I beg to return you on their part their most hearty thanks for the way in which you have received the toast proposed by the President. [*Applause*.]

Dr. McDONNELL, President of the Royal College of Surgeons, on rising was received with hearty applause. He said: I also return my sincere thanks, on behalf of the corporation that I represent, for the manner in which you have drunk our healths. The College of Surgeons has never been wanting, and I hope never will be wanting, in aiding any movement that tends to raise the honour and dignity of the profession. We look, therefore, with great satisfaction on the formation of this Branch of the British Medical Association, and I hope it may go on and be prosperous. The speeches this evening have been admirable, and I will not try to rival them; but before sitting down, with your permission, I will propose a toast which, I venture to say, in spite of what the President has said about another toast, will be the toast of the evening. I propose to you the health of Dr. Duffey. There is not one of us who does not know the services that Dr. Duffey has rendered in the formation of this Branch. [*Cheers*.] The tact, the zeal, and the good sense that he has displayed in the accomplishment of his task could not have been excelled. It was for a long time feared that a Branch Association of the British Medical Association would be regarded as inimical to, if not in some degree antagonistic to, our own Association. He has called it into being, and I hope it will go on and prosper under his auspices, and that it will not prove in any way inimical to, but on the contrary beneficial to, its friend the Irish Medical Association. I propose to you the health of Dr. Duffey; and I call on you to drink his health with enthusiasm.

The toast having been most warmly received,

Dr. DUFFEY, on rising, was received with prolonged applause. He said: The President of the Royal College of Surgeons in Ireland has taken me quite by surprise by the kind way in which he has mentioned my name. I can only say that any efforts that I have made in connection with the establishment of a Branch of the British Medical Association in Ireland have been amply repaid by our meetings of this afternoon and this evening. I thank you all, gentlemen, very sincerely for the way in which you have drunk my health; and I may be allowed especially to express my thanks to the President of the British Medical

Association and to Mr. Ernest Hart, for their presence here to-day. I think it a very great personal compliment. I repeat that any trouble that I have taken in this matter has been amply repaid by the success of our meetings and by the kind way in which my name has been mentioned.

The CHAIRMAN: I have now to give you a toast to which I am sure you will all respond heartily, namely, the South and the North of Ireland Branches of the British Medical Association; and with it I associate the names of Dr. Curtis and Dr. Cuning, the distinguished Presidents of those Branches. We must admit that Cork took the lead of us by establishing its important Branch before we formed ours. It showed us a good example. I think we owe a debt of gratitude to both these gentlemen for having done us the honour of coming to attend our meeting of to-day, and of being present at this entertainment.

The toast was duly honoured.

Dr. CURTIS: It gives me great pleasure indeed to answer for the South of Ireland Branch of the British Medical Association. When I received your invitation, I determined that, no matter what inconvenience it might involve, I would be present at your meeting. [*Hear, hear*.] I was amply repaid to-day by hearing the able and eloquent address of your late President; and I have been still further rewarded to-night by hearing the various speeches to which we have listened. It is, I am sure, a great honour to be the President of any Branch connected with the British Medical Association; but I take especial pride in being the President of the first Branch of that Association that was formed in Ireland—not that I speak of it as the first in point of numbers, but as the first established in the order of time. I may say that I do not believe, at this present moment, there would be a Branch established in Ireland but for the unceasing and untiring energy of my friend and colleague Dr. Macnaughton Jones. [*Hear, hear*.] When it was first proposed to establish a Branch in the South of Ireland, a meeting of the profession was called, and they said—"No, it will not succeed"; but Dr. Jones said—"It must succeed". Then they rallied round him; and we have now in the South of Ireland a society which is the largest outside of Dublin, numbering close on one hundred members. I am justly proud of being President for this year of that society. So prosperous is it, that we intend, in the year 1879, to entertain the parent society and all the branches of the medical profession who will do us the honour of coming to Cork. [*Applause*.] I believe Cork to be peculiarly adapted for that purpose beyond other places in Ireland. We have the beautiful Lakes of Killarney and the romantic scenery of the harbour to show you; and we shall have the co-operation of various bodies, including the Queen's College, Cork, which, through the kindness of its President, Dr. Sullivan, will be thrown open on the occasion. All I can say is, that if we do not show you the hospitality for which the South is famed, I shall be very much surprised. We shall certainly receive you with *Cead mille fearde*. [*Applause*.] I beg again to thank you for the toast, and your kindness in mentioning my name.

Dr. CUNING: I rise to return you my best thanks on behalf of the North of Ireland Branch of the British Medical Association, which has been very recently founded. In the formation of that Branch, we have been content—as we are content in a great many other things—to follow, at a respectful distance, the action of our Dublin brethren. We did not found it until after we discovered that a Branch had been formed in Dublin; but, although somewhat late in its foundation, our Branch bids fair to be a prosperous member of the great Association in whose prosperity we are all so deeply interested. We are all deeply interested in it, because it is a body that is capable—and, I think, alone capable—of reflecting faithfully the opinions of the medical profession at large. We know that the great corporations that have been in existence for many years in connection with the medical profession have done great service for it, and have represented its opinions very faithfully to the Government of the country. But year by year our relations to the Government became closer and closer, and it became more important than ever that the medical profession should speak as an united body. This now is effected by the British Medical Association; and it is very desirable that we should draw the bonds of union between all its branches as close as possible. I am happy to say that our Branch bids fair to be prosperous and successful. It has been personally very gratifying to me to come up to Dublin and to meet so many old friends amongst the members and elders of the medical profession here; and it is also especially gratifying to me to sit under the presidency of a man so universally respected in the surgical world as the distinguished President of your Association. [*Applause*.]

The CHAIRMAN: My list of toasts is now drawing to a close, but the toast I am about to bring under your notice is one to which I know you will all warmly respond. I have no doubt whatever about it. I

give you "Our Visitors", and with that toast I couple the names of Mr. Ernest Hart and Dr. Macnaughton Jones. [Applause.] A good thing cannot be said too often. Thanks have been already expressed to Mr. Ernest Hart for his great kindness in coming over to Ireland; and as your President I now tender to him again our best thanks for his great kindness in doing so, when, I am sure, it must have been a great inconvenience to him to come over to Ireland. [Applause.] I also tender your thanks to Dr. Jones for his kindness in coming up from the South of Ireland to attend our meeting and banquet. Mr. Hart's action in the present instance is just like every other act of his in respect of matters connected with the medical profession in Ireland. One of the most important features connected with the British Medical Association is its JOURNAL, and we all know how brilliantly and honourably that journal is conducted. We all know that when an Irish question is put forward in that journal it is not put in a dark corner where no one can read it, but always receives a prominent place, and the kindest and best remarks are made on it. We are indebted to Mr. Hart for a great deal, and the parent Association also owes him a great deal. I therefore give you "Our Visitors", coupling with the toast the names of Mr. Ernest Hart and Dr. Macnaughton Jones. [Applause.]

The toast was most cordially received.

Mr. ERNEST HART, on rising, was received with warm applause. He said: So great is the hospitality and so manifold are the attractions of Dublin, that to every visitor to that city I think there can be but one regret, and that is the regret which arises when he leaves the city, and there is even then the consolatory hope of a speedy return. That, sir, I am sure was the main feeling in the minds of every one of the visitors to Dublin ten years since, when you gave to the members of the British Medical Association so memorable a welcome in 1867. And on returning to-day I was forcibly reminded by the words of the Vice-President of the College of Physicians of the expressions with which the President of the British Medical Association in that year, the illustrious Dr. Stokes, whose name will always be affectionately cherished and venerated in the Association, welcomed us on that occasion, because they seemed to me to express with characteristic earnestness and precision the best sides of our Association and those which give it the strongest claims to the adhesion of its Irish members and, indeed, of all its members. He said: "Your society is altogether peculiar in its organisation, and one in which we recognised the union of the profession in the three kingdoms for objects that are good, and consequently great. It has in good earnest sought to raise the status of medicine by the labours of love, on the one hand, and by those of science, on the other." Dr. Little expressed precisely those two aspects of the Association: its scientific aspect, on the one hand, and its social aspect, which regards the common interests of the profession, on the other." Dr. Little also very happily expressed the change which has taken place by saying that to-day the Irish members entered into complete physiological relation with the British Medical Association by the constitution of this Branch. Dr. Wilkinson, the respected President of the Association, has again referred to the three methods by which the Association progresses; namely, the representation of its members on the General Council and Committee of Council; the action of the local Branches; and the connection of members with the Association through the weekly JOURNAL of the Association—the BRITISH MEDICAL JOURNAL. Notwithstanding many efforts and much correspondence which I have had with leading members of the profession in Dublin on the subject at the date of and since our general meeting in Dublin in 1867, the only direct connection which the Irish members have had with the Association until quite lately has been through that which has been just described as the third bond of union between us—the JOURNAL; nevertheless, it has been a great source of satisfaction to me that, in the course of the ten years that have elapsed since I first became editor of the JOURNAL, the number of members has run up from a very small number to several hundreds, until now it is nearly, if not quite, five hundred, which is more than a third of the whole profession in Ireland. We have every reason to hope that, now that the members of the profession here have direct connection with the Association in all its powers and forms of usefulness, the Association will take still wider and firmer root here; and that the profession in Ireland will be united with the profession in England and Scotland for all generous purposes by a direct, organic, and immediately active union. It has been to me a very great pleasure to attend here to-day and to take part in welcoming the formation of those three Branches in the north, the south, and the east of Ireland, and I hope that we may all at no distant day have the pleasure of welcoming the formation of a Branch in the west of Ireland. [Applause.] At any rate, the pleasure of attending such a meeting as this, so full of happy omens, is much

more than a compensation for the fatigues of crossing the Channel; and I hope that the Irish members of the Association will favour us by returning the visit and by attending numerous at our annual meetings. I feel a well grounded confidence in assuring them that, at all meetings of the Association throughout the United Kingdom, they will always receive from the English and Scottish members a most hearty welcome, and find the leaders of the Irish profession amongst the most honoured guests. [Applause.]

Dr. MACNAUGHTON JONES: I assure you that it has given me very great pleasure to attend the first annual meeting of this Branch of the British Medical Association. So many good reasons have been brought before us to-day in proof of the advantages which must follow to the profession in Ireland from the formation of Branches of this great Association in our midst, that it is quite unnecessary for me now to dwell on the reasons which induced me to attempt the formation of a Branch in the South of Ireland. But I must say that when I determined to take in hand that movement I was actuated by only one motive, namely, an anxiety to spread among my professional brethren a greater desire, if possible, than at present prevails amongst them for the promotion of scientific knowledge. I was actuated by no political motive. I felt that throughout the provinces of Ireland there has been a mass of latent scientific power which ought to be called forth; and I believed that by the formation in this country of such Branches of the British Medical Association as exist all through England and in most parts of Scotland, we should promote the advancement of medical knowledge in Ireland. It was for that reason alone that I took in hand the formation of the South of Ireland Branch; and I was ably seconded by some gentlemen who have worked at my shoulder in the matter from the first moment to the present. I should be wanting in gratitude if I did not mention the name of a gentleman who has been all through most efficient in connection with the South of Ireland Branch, and who, although young, has already gained for himself a wide reputation in medical science—I mean Dr. Atkins of Cork. Dr. Curtis, our worthy President for this year, has referred to my exertions, but I assure you that I should have been nowhere had I not been seconded by our efficient and able secretary Dr. Atkins. It would ill become me at this late hour to detain you with any remarks as to the advantages which must accrue to our profession from the formation of Branch Associations in Ireland. I agree with Mr. Ernest Hart in hoping sincerely that we shall yet have a fourth branch society for Connaught, so that all the four provinces of Ireland may be represented in the British Medical Association; for we know that we have already in Connaught a Queen's College, ably officered, and we cannot fail to realise the fact that there exists throughout that province a vast amount of medical knowledge, which is not at present brought forward. There is one point to which I wish to allude. It is, of course, important in the formation of Associations such as this that care should be taken not to collide or to interfere in any way with the interests and the working of other Associations. I candidly confess that, when our Branch Association was first formed, I felt that it might be considered antagonistic to a kindred Association of a scientific character which already existed in Cork. But competition is always the life and soul of business, and competition has already done good in a scientific point of view in Cork, for we have stimulated that other Association, which was becoming more or less a dead letter, and now we have two Associations where previously only one existed, and that, perhaps, of a very slow character. Just one word more. We have taken in hand a great work. We intend to invite the British Medical Association to Cork in 1879. That invitation has been already put on record in the JOURNAL of this Association. But we are fully alive to the responsibility of that movement. We know that in bringing so vast an Association to the South of Ireland we undertake a task which it may not be easy to accomplish in such a manner as we wish. Dr. Curtis told you of our beautiful scenery and surroundings, and of our lovely lakes, but we feel that there are a great many other matters which enter into the success of the annual meeting of so important an Association as our parent society is. I am one of those who think that, if the annual meetings of the Association were to merge into mere social gatherings, they would become something which would not be valued by the members of our society generally. We must have scientific matter, and I am very glad of having this opportunity of saying to our Dublin friends that I hope they will come manfully forward and help us on the occasion with scientific material, and give us in that respect such assistance as will enable us worthily to represent Ireland, and not be behind any other city in the United Kingdom in giving to the Association not alone a hearty welcome and social amusement, but also such scientific food that they will not leave the southern metropolis without carrying home with them useful knowledge, besides having enjoyed an agreeable holiday. I shall not

detain you any further, but beg again to thank you very sincerely for the very unexpected honour you have paid me by coupling my name with the toast [Applause.]

The CHAIRMAN: The last toast on my list is not the least, as I am quite sure you will think when I mention it to you. I give you "The Press". The Press in this country has been always foremost to assist the oppressed. It has been always foremost in lending its aid to the advancement of science and knowledge; and I can say with truth that on every occasion on which it was in its power to do so, the Press has manfully stood by our profession. I therefore ask you to drink, and warmly drink, the toast of the Press, and I couple with it the names of Dr. Patton and Dr. Jacob. [Applause.]

The toast was duly honoured.

Dr. PATTON, in responding, said: The Press would forfeit its claim to the confidence and support of the patriotism and intelligence of the city and country if it did not assist in advancing the interests of a profession to which the world owes so much—a profession which is the brightest and best of all professions.

Dr. JACOB: There is an advantage in being obliged to speak after having heard the ideas of those who have gone before me. I have listened with great attention to the many admirable speeches which have been made this evening. I am but a young medical man, and yet I recollect the time when there were but few representatives of medicine connected with the Press. But, as a medical man, I feel pleasure in observing that the medical profession has now many competitors for its good word and its patronage. [Hear, hear.] Its influence upon society is more beneficially felt than ever; and the JOURNAL of the parent Association, with which this Branch is connected, proves in the strongest way that the profession not only deserves from the public the most complete recognition, and from the Press every assistance which the latter is capable of affording, but that it is capable of reciprocating in the most ample manner the good offices of both. Sir, my friend Dr. Patton represents a much more influential and useful arm of the Press than I do. [Vv.] He is able to place the Association before the general public in a way that neither my eminent confrère, Mr. Ernest Hart, nor myself could do. Our position is amongst you who know what we can do, and who are thoroughly conversant with every word that we publish; but the daily press is more influential in placing our profession in a right position before the world. All I can say is, that as long as the medical profession applies itself to the high objects which are represented by this Association, namely, the advancement of science and the good of the general community, not only the Press which is specially interested in the profession, but also that which is devoted to the interests of the general public, will give it their support. The profession has never occupied so excellent a position in the public estimation through the columns of the fourth estate as it now occupies. From the pre-eminence which I see given to medical matters in the columns of the leading journals, it bids fair, I think, to occupy the best position amongst the learned professions of our country. I think, therefore, that what this Association has to do, and what we all have to do, is to cultivate those objects which recommend themselves to the esteem of the public at large; and you may be perfectly certain that if you follow that course you will receive the best assistance that the Press is capable of affording to you. I thank you very much for the manner in which you have conducted me with the toast. [Applause.]

The proceedings then terminated.

#### MEDICAL EDUCATION IN THE UNIVERSITIES OF OXFORD AND CAMBRIDGE.

WE are compelled to defer, from want of space, further remarks on the subject of medical education in Oxford, to which attention has been recently directed in our columns. We have, however, received this week various important contributions towards the solution of the question raised: one is in the form of a letter, addressed by an eminent German Professor to a friend in London; and another, to which still more value will be attached, the early sheets of a pamphlet about to issue from the pen of Dr. Michael Foster of Trinity College, Cambridge, discussing the second branch of the subject which we have opened, namely, the state of medical education at Cambridge, indicated in our first comment as calling also for discussion. Dr. Michael Foster's pamphlet has a direct bearing upon the state of medical education in Oxford, as well as in Cambridge. Meantime, we only note this significant fact that, whereas in Oxford clinical teaching has been regarded as an impossible point, in Cambridge the teaching is mainly clinical and practical, and the courses most remarkable for their deficiency are certain theoretical courses.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At the ordinary meeting of the College on January 30th, Drs. Handley Jones, Munk, Burdon Sanderson, and Priestley were elected Councilors.

The following by-law was repealed. "Every candidate who has prosecuted his studies abroad, whether in part or to the full extent, shall nevertheless bring proof of his having attended during at least twelve months the medical practice of an hospital in the United Kingdom."

Exemption from re-examination in Chemistry and Materia Medica was recommended by the Council in the case of candidates for the licence of the College who had previously passed in those subjects at an University in the United Kingdom, in India, or in a British colony where the degree or a licence to practise was granted.

It was recommended that the following general principles should be adopted in reference to the prize of one hundred guineas offered for the best essay on Hydrophobia: That the subject should be the Causes, Prevention, and Treatment of Hydrophobia; that special value should be given to original researches; and that the prize should not be awarded unless there were an essay of sufficient merit.

It was reported that great improvement had been shown by the candidates in the examination in Chemistry.

#### THE AMENDMENT OF THE MEDICAL ACTS.

Dr. LUSH has printed the Bill which he has reintroduced, at the instance of the Medical Alliance Association, for the amendment of the penal clauses of the Medical Act in such a form as to protect the public from the deception now practised with impunity, by a great number of persons holding fictitious and worthless diplomas from bogus universities or falsely assuming medical titles. This, which was the avowed object of medical legislation, and set forth as such in the preamble of the first Medical Act, has, as is well known, been frustrated by the defective wording of the fortieth section; and the results have been equally prejudicial to the profession and to the public. The Bill appears to be framed in harmony with the resolution on the subject carried at the last general meeting of the British Medical Association. Dr. Carpenter, the Honorary Secretary of the Medical Alliance Association, has forwarded to us a circular which is issued with the Bill, and which concisely sets forth the particulars of a number of cases, showing the conflicting decisions of magistrates and judges arising out of the defective wording of the Act; and in this brief abstract may be seen how thoroughly incapable the Act, as at present worded, is of affording protection in this most important respect either to the public or to the profession.

#### THE PRIVILEGES OF THE PROFESSION.

A BILL to amend the law relating to dental practitioners has been introduced by Sir John Lubbock and Dr. Lush, having the useful object of providing registration for persons specially qualified to practise as dentists in the United Kingdom. Very short notice has been given of the second reading, and no time has yet been afforded to the bodies specially concerned, such as the medical profession at large and the Association of Surgeons who practise Dentistry, to consider the clauses. The Bill was set down for second reading on Wednesday; but, upon representations being made to Sir John Lubbock to that effect, the second reading has been postponed to Wednesday next. This, however, is still too short a time to allow due consideration of the clauses of this Bill by those whose interests are affected; and we trust no objection will be made to further postponement in order to enable satisfactory arrangements to be arrived at, by which a measure so useful in its objects may be carried through in a form which is not open to the same objections palpable on the face of this Bill as it at present stands. The effect of the third clause of the Bill would be to take away the privileges of all surgeons and general practitioners practising dentistry, and to prohibit them from calling themselves dental surgeons, or by any other name implying that they are qualified to practise dentistry. This is open to obvious objection: it is contrary to all precedents, whether of the Apothecaries' Act or the Pharmacy Act. The rule of law and the rule of reason always has been, that the greater includes the less; and it is obvious that a surgeon fully qualified cannot be debarred by this Bill from practising the branch of surgery known as dental surgery, any more than from practising ophthalmic surgery or aural surgery. As the Bill stands, it reads like an

inconsiderate attempt to cut off from surgery one of its most ordinary departments. If this precedent were established, we might expect to see a register created for oculists, for aurists, and for obstetricians; and fully qualified surgeons debarred from practising in these departments, in the same way as this Bill proposes to prevent fully qualified surgeons from practising dental surgery. It is hardly possible to suppose that this was the intention of the framers of the Bill; but that would certainly be its effect. A meeting of the Parliamentary Bills Committee will be at once summoned to consider this Bill.

### ARMY MEDICAL SCHOOL, NETLEY.

THE thirty-fifth session of this school was brought to a close on Monday, the 4th instant; and while we observed that a considerable number of strangers were present from the neighbourhood, as well as the military and medical officers doing duty at the Hospital, we were sorry to notice that no representative from the War Office nor from the India Office nor the Admiralty was there to give countenance and moral support to the work of the School, and personally to give away the prizes to the successful competitors.

Surgeon-general Dr. Massy, C.B., the Principal Medical Officer at Netley, presided, and presented the Martin Memorial Medal at the conclusion of the proceedings.

The session has been attended by 53 candidates—namely, 25 for the army, 19 for the Indian, and 9 for the naval medical service. There were also present two surgeons of the Indian medical service, home on furlough, who availed themselves of the opportunity of going through the practical work of the school, and another surgeon belonging to the Quebec Royal Artillery was also present and worked most industriously during the session.

Of the 25 army candidates, one of them failed to obtain the necessary number of marks to qualify him for admission to the service. Out of a maximum of 6,900 marks obtainable he gained only 2,122, a number less by 178 than what is just sufficient to place a man in the list of successful competitors; and out of 3,500 marks obtainable at Netley he gained only 872. It is well that these results should be known amongst candidates, because we have reason to believe that an impression has been gaining ground of late that, when once a candidate has passed the London examination, he has no need of any further exertion to maintain his place at Netley, and so pass into the service. He must gain at least *one-third* of the maximum marks obtainable by the combined results of the London and Netley examinations.

Two candidates only out of the 53 especially distinguished themselves in the work of the school. These were Mr. S. J. Thomson and Mr. R. N. Campbell, both of the Indian medical service. Mr. Thomson gaining both the Herbert prize (£20) and the Martin Memorial (gold) Medal. This is the third competition that has taken place for this last-named honourable distinction, instituted in memory of the late Sir Ranald Martin, K.C.B. It is open to the competition of all the candidates of the three services attending the Army Medical School during each session, and is awarded to the candidate who most of all distinguishes himself in Military Medicine. On this occasion 22 candidates competed for the medal—namely, seven army, four navy, and eleven Indian candidates, a special examination paper having been set for this competition by Professor Maclean. The final struggle mainly lay between Thomson (979), Campbell (945), and Brander (895), of the Indian service; Young (865), of the army; and Porter (861), of the naval candidates. Mr. J. S. Thomson became the successful competitor, and received the medal from Surgeon-General Dr. Massy, C.B., amidst the acclamations of his fellows.

## ASSOCIATION INTELLIGENCE.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE next meeting will be held in the Examination Hall of the Queen's College, on Thursday, February 14th, 1878.

The Chair will be taken by the President, SAMPSON GAMGEE, Esq., at 3 o'clock P.M.

The following papers are promised.

Mr. Lawson Tait: Fifty Cases of Ovariectomy.

Mr. Lloyd Owen: Nystagmus.

Members are invited to exhibit patients, pathological specimens, new drugs, or instruments, at the commencement of the meeting,

JAMES SAWYER, M.D., { *Hon. Secretaries.*  
EDWARD MALINS, M.D., }

Birmingham, February 7th, 1878.

### SHROPSHIRE AND MID-WALES BRANCH.

A QUARTERLY meeting will be held at the Salop Infirmary on Tuesday, February 12th, at 6.30 P.M.; J. RIDER, Esq., President, in the Chair.

The Secretary will feel obliged to those members who intend to read papers if they will signify the same to him before the day of meeting.

HENRY NELSON EDWARDS, *Honorary Secretary.*

Shrewsbury, January 30th, 1878.

### LANCASHIRE AND CHESHIRE BRANCH.

THE first intermediate meeting of this Branch will be held at the Town Hall, Oldham, on Tuesday, March 5th, at 3.30 P.M.

Dr. W. H. Broadbent (London) has kindly consented to read a paper on the Mechanism of Speech and Thought as illustrated by Pathology.

Members wishing to read papers or to exhibit specimens are requested to communicate with the Honorary Secretary as soon as possible.

Dinner will be provided at 6 o'clock.

D. J. LEECH, M.D., *Honorary Secretary.*

96, Mosley Street, Manchester, January 31st, 1878.

### METROPOLITAN COUNTIES BRANCH.

AN ordinary meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesday, February 27th, at 8 P.M.; when Mr. T. HOLMES, F.R.C.S., will read a paper on Provident Dispensaries, to be followed by a discussion.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*  
W. CHAPMAN GRIGG, M.D. }

London, February 7th, 1878.

### PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

AT a meeting of the Committee of Council, held at the Freemasons' Tavern, Great Queen Street, London, on Wednesday, January 9th, 1878: Present, Dr. R. W. FALCONER (President of Council), in the Chair, Dr. E. Wilkinson (President), Mr. W. D. Husband (Treasurer), Dr. T. Clifford Allbutt, Mr. Alfred Baker, Mr. J. W. Baker, Dr. M. M. De Bartolomé, Dr. L. Borchardt, Mr. E. C. Board, Mr. Callender, F.R.S., Dr. Alfred Carpenter, Dr. Charles Chadwick, Dr. J. W. Eastwood, Mr. R. S. Fowler, Dr. E. L. Fox, Dr. C. Holman, Mr. A. Jackson, Mr. Frederick Mason, Mr. F. E. Manby, Dr. E. Morris, Dr. C. Parsons, Mr. R. H. B. Nicholson, Dr. A. P. Stewart, Dr. E. H. Sieveking, Dr. W. F. Wade, Mr. C. G. Wheelhouse:

The minutes of the last meeting were read and found correct.

Resolved: That the twenty candidates whose names appear on the circular convening the meeting be elected members of the Association.

Read letter from Dr. Wilson Fox, of which the following is a copy:

"67, Grosvenor Street, W., December 21st, 1877.

"My dear Sir,—After some consideration, I have resolved to ask you to bring the following question before the Council of the British Medical Association, and to favour me with a reply to it.

"The question which I desire to put is this: 'Are women to be permitted in the future to attend the meetings of the Medical and Surgical Sections of the annual and other meetings of the British Medical Association, and to take part in the discussions at such meetings?'

"I had believed that this question was answered in the negative by a large majority of the Association a few years ago.

"At the last meeting, held at Manchester, a lady was present, and spoke in a discussion in the Section of Medicine.

"As I do not intend to be a member of any society where medical topics are debated in public between men and women, I shall be glad to learn the decision of the Council in this matter, reserving to myself the right to publish this inquiry and the reply which I may receive.

"I remain, my dear sir, respectfully yours,

"Francis Fowke, Esq."

"WILSON FOX.

Resolved: That Dr. Wilson Fox be informed that the Committee of Council have no power to prevent ladies who are members of the Association from attending the meetings of the Association.

Resolved: That the minutes of the Journal and Finance Committee of to-day's date be approved, and the recommendations carried into effect.

Resolved: That a seal for the Association be adopted.

The President of Council then reported that the subcommittee appointed to consider the design for a seal for the Association had decided upon recommending the head of Sir Charles Hastings, the founder of the Association.

Resolved: That the design for the seal proposed by the subcommittee be adopted.

Resolved: That the terms of the lease of 161, Strand, having received the approval of the Solicitor to the Association, Mr. J. R. Upton, be, and they are hereby accepted, and that the common seal of the British Medical Association be affixed to an indenture dated the day of \_\_\_\_\_, 1877, made between Sophia Webb of the one part, and the British Medical Association of the other part, being the counterpart of a lease of a message or tenement and premises situate and being No. 161, Strand, in the county of Middlesex, for a term of twenty-one years from the 29th September, 1877, at a yearly rent of £320.

Resolved: That the Committee of Council insure for £3,000, and also for one year's rent (£320) in addition, so that in event of fire the Insurance Company pay the rent, as well as damage by fire.

The minutes of the Arrangement Committee for the annual meeting to be held at Bath were read, and it was

Resolved: That the minutes of the Arrangement Committee of to-day's date be approved, and the recommendation be carried into effect.

The minutes of the Habitual Drunkards Committee of to-day's date were read.

Whereupon an amendment was moved:

Resolved: That in the event of the Home Secretary not being prepared to introduce a Government measure, this Council will be prepared to give support to any reasonable measure which may be introduced by a private member.

#### STAFFORDSHIRE BRANCH: ORDINARY MEETING.

THE first ordinary meeting of this session was held at the North Staffordshire Hotel, Stoke-upon-Trent, on Thursday, November 28th, 1877; present, Dr. ARLIDGE, President, in the chair, and twenty-five members.

*New Members.*—The following members of the Association were duly elected members of the Branch: Dr. J. A. Gailey (Leek); Mr. J. C. Garman (Wednesbury); Mr. M. Taylor (Cannock); Mr. George Lowe and Dr. W. G. Lowe (Burton-upon-Trent).

*Pathological Specimens.*—Dr. JOHNSON exhibited an Acephalous Fœtus.

Mr. ALLCOCK showed two specimens of Extracapsular Impacted Fracture of the Left Femur. Both patients were over seventy years of age; one being a male, and the other a female. Before death, osseous union was complete.

Mr. VINCENT JACKSON showed a portion of the right upper jaw of a man, which had been recently removed by him on account of extensive Epithelial Disease involving the mucous membrane covering the palate and alveolar processes.

*Communications.*—Dr. J. H. TYLCOATE read a paper, in which he narrated the histories of some recent cases.

Mr. FOLKER read a paper on a successful case of Excision of both Knee-Joints.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

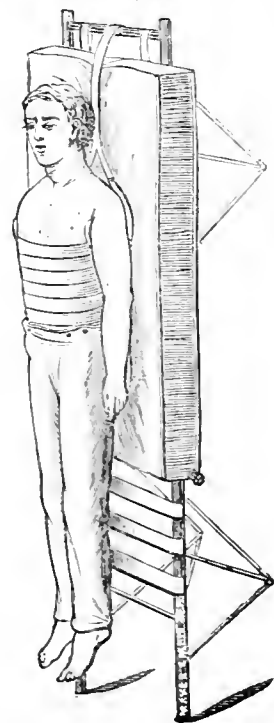

FRIDAY, JANUARY 25TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Sayre's Plaster of Paris Jackets in Spinal Disease.*—Mr. BERKELEY HILL brought, for the inspection of members of the Society, a selection of twelve patients with angular and lateral spinal curvature, for which they were wearing Sayre's plaster jackets. In doing this, he avoided criticism of the correctness of the theoretical grounds on which Dr. Sayre explained the mode in which the spine was affected, and also the description of the method of application, observing that those matters were set forth in Dr. Sayre's *Spinal Diseases*, etc. (Smith and Elder, 1877). He confined himself to the results which had been gained by six months' experience of the mode of treatment. The cases exhibited that evening had been mainly under his own care, but some were from the hospital patients of his colleagues, Messrs. John Marshall and Arthur Barker. Four cases from the Cheyne Hospital for Incurable Children were exhibited by Mr. James P. Bartlett. The

cases comprised examples of angular and lateral curvature of various situations and degrees, some wearing the jury-mast to support a curve in the upper dorsal region, one with lumbar abscess and sinus. The first case treated in University College Hospital after Dr. Sayre had himself demonstrated his method, was put up on July 13th. The patient immediately lost the pain in her back, which up to that time had been too severe to permit of her walking about or sitting up for more than half an hour at a time; and she went for a walk out of doors of her own accord the same day. Two days later, she went into the country till November. She at once discarded invalid habits; and in the latter part of her stay nursed a sick sister. The jacket put on in July was worn till nearly Christmas; it was then removed, and a poroplastic felt corset moulded on to the trunk while the patient was suspended. This did not appear to give sufficient support, as the pain in the back had returned frequently and increasingly. Hence Mr. Hill exhibited the patient wearing her corset—an excellent fit—to show that this material did not embrace the trunk with sufficient immobility to support it effectually. Mr. Hill next read the notes of the second case to which the plaster jacket was applied in University College Hospital, on July 14th, 1877, by Mr. Marcus Beck. This was a case of very acute character and with well marked symptoms. The patient could not walk fifty yards without his crutches, and only a very short distance with them, on account of the severe pain produced. On being encased, he walked out of the hospital easily, carrying both crutches in one hand. One month later, he was able to walk nine miles. He wore the shell for three months; it was then removed, and he had remained quite well ever since. Mr. Hill then briefly described the case of the daughter of a medical man in Cheltenham, who was encased by Dr. Sayre himself at Guy's Hospital on July 25th, 1877. She had been suffering for eight years from injury to the upper dorsal region, causing collapse of the upper part of the column, great protrusion both backwards and forwards, complete inability to stand or walk, constant pain, and at one time, paraplegia. On January 23rd, 1878, her father wrote: "She began to improve from the first, and has continued to walk with increasing strength ever since. She has literally had no pain at all. She does her share of play, and goes regularly to school." Mr. Hill then summed up the benefits which six months' experience of the plaster shells had shown. 1. Pain was at once arrested. 2. So far as the spine was concerned, the patient was immediately able to sit upright and to walk about. 3. Control of the lower extremities, when lost or diminished, was rapidly improved or restored. 4. Abscesses steadily closed. 5. The spinal column lost

much of its abnormal curve and consolidated in the improved position. 6. In lateral curvatures, a permanent increase of stature was often obtained. 7. Finally, by Sayre's jacket cure was more rapid and less irksome than by any other method. Mr. Hill remarked that caution was necessary to prevent the patient from attempting too much exertion; even when thoroughly supported in the shell, most patients required rest through some part of the day. In conclusion, Mr. Hill mentioned several small modifications in the method of application, which had been found to be improvements. The chin-piece should be more deeply cupped at the chin and well lined with thick felt. The suspending straps should be attached just in front of the zygoma and behind the ear. The axillary slings should be padded firmly, and stiffened, so as to take the form of the cross of a crutch. To receive adult or heavy patients from the gallows without risk of bending the plaster shell before it had set, Mr. Hill had contrived a table, swinging at its middle like a toilet looking-glass. This, carrying the slack air-bed, could be pushed against the patient while suspended; two large hooks were slipped under the armpits and hitched to the top of the table. The patient, thus attached to the table, was freed from the gallows. The table was lowered from the vertical to the horizontal position, and the patient sank

without strain or jolt into the slack air bed, which supported the plaster evenly on all sides till it set. Messrs. Mayer and Meltzer, who had

constructed the table, had also made a light folding frame to answer the same purpose. To cut up or trim the plaster shells, a carpenter's small dovetail saw and a pair of French vine-dresser's shears were the handiest tools.—[The accompanying woodcut represents a patient attached to the folding frame of Messrs. Mayer and Meltzer, and reclining against the slack air-bed, previously to being lowered to the horizontal position.]

The PRESIDENT said the practical character of Mr. Hill's paper added considerably to its value. In cases at St. Bartholomew's Hospital, the difficulty of removing patients from the upright to the lying-down position had been experienced, and he had overcome it by a table very similar to that shown by Mr. Mayer.—Mr. T. SMITH remarked that the table was of great assistance. He had seen a case in Dr. Sayre's hands in which the bandages were broken during the movement from the upright to the horizontal position. In private cases, he merely asked for a leaf out of the dining-room-table; that answered every purpose of the swinging table. As regarded the pads which had to be used for the female breast and the abdomen in both sexes, he always had recourse to air-pads with a stopcock; the air could then be let out before the dressings were removed. He highly praised Dr. Sayre's method of treating cases of spinal disease.—A VISITOR, whose child had been under Dr. Sayre's treatment, said that he had found great difficulty in removing the plaster splints, and had consequently after a time adopted Hides' splints, with which the child could walk about without growing faint.—Mr. C. LUCAS had not yet found any inconvenience arise from the suspension of the patients necessary to the application of the jacket. Of twelve cases so treated by him, four were cases of lateral, eight of angular curvature. Three times he had had to undo the splint before cure was complete; once, in a child put up by Dr. Sayre himself at Guy's Hospital, the skin covered by the splint became covered with psoriasis. Arsenic being given, in three weeks the child recovered from its skin-affection, and the splint was reapplied. In a second case, desquamation occurred in the skin covered by the splint. In the third case, the splint was removed for the treatment of pediculi. He had not seen sores produced by pressure, and thought they could only come where the bandage was applied badly, and where no pad was put over the spines of the vertebrae. He also spoke in highly laudatory terms of Dr. Sayre's method of treatment.—Mr. BARWELL was the first to put on the bandage in this country, which he had done before Dr. Sayre came to England. He had now used it in seventeen cases; and in only one case had the bandage had to be removed. It was on that occasion done by the house-surgeon for difficulty of breathing. It was replaced very carefully after three days, and was then worn with comfort. The angle of the spine did not improve subsequently more than it did at the first suspension. The apparatus shown by Messrs. Mayer and Meltzer was ingenious, but not usable in private practice. At his own house, he used a sofa and a stiff sheet; the patient, being placed in the sheet, was gradually lowered to the sofa. Sayre's bar, when used for suspending the patient, pressed on the axillary nerves; in the suspender used by himself, the pressure was made by two pieces instead of by one; and, as the pressure was thus made chiefly inwards against the chest-wall, heavy people even might be suspended without hurt to themselves. He did not find it necessary to pad the spines of the vertebrae; he simply lifted the bandage from the spines at the time of its application, and subsequently replaced it by a piece of cotton-wool in each axilla, and another large pad between the mammae. He related the case of a man who, with angular curvature, had for four years had asthmatic breathing; and who, directly the splint was applied, lost the asthma.—Mr. BARKER said that the troubles with the plaster corset witnessed by himself in cases at University College Hospital were chiefly the following. Chafing occurred to a marked degree in two cases. The first was that of a very young child (affected with angular curvature), who, after a fortnight's application of the jacket, had a slough of some size over the most prominent spine. It rapidly healed, however, directly the splint was removed. In the second case, a slough also formed after the jacket had been worn six or seven weeks. This child had, however, been otherwise greatly improved by the jacket, and the slough healed when the bandage was removed. The jacket in the first case was shown to Dr. Sayre's son, who found it an excellent one, without any fault that he could detect. Perhaps, the cause lay in the early age of the child and the consequent small size of the pelvis, upon which the corset could not take a good grip, so admitting of more wriggling. In the second case, too, no cause in the plaster-case could be found for the sloughing spot. One ought to be aware of possible troubles that might occur. At the same time, he was confident that other corsets which he had applied had been productive of unmitigated good, as in the case exhibited by him there that evening.—Mr. GOLDING-BIRD had treated eighteen cases, and had seen a great deal of good result in all of them. No

harm ensued, except in some of the early cases, from chafing. The whole treatment lay in the swinging of the patient: the plaster-cast simply kept the body extended when the swinging had effected its good by lifting the heavy head and arms, which were pressing on the weakened spine. The treatment consisted in the fact of its being an extending, in contradistinction to a pushing force, and it afforded that which Mr. Hilton had contended should be the aim in such cases—namely, to afford physiological rest to the part. Felt should not be used for the formation of the cast; it did not retain sufficient stiffness to give the necessary support.—Mr. B. HILL briefly replied.

*Erythema Multiforme*.—Dr. TILBURY FOX exhibited a patient suffering from this disease. The skin exhibited all the varieties of erythema usually described in the text-books.

## CORRESPONDENCE.

### ADMISSION OF LADIES TO THE MEETINGS OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—I cannot believe that the resolution of the Committee of Council communicated to Dr. Wilson Fox, and published by him in your issue of to-day, represents the true position of the British Medical Association with regard to women.

The terms of the resolution, I may remind your readers, are, "that Dr. Wilson Fox be informed that the Committee of Council have no power to prevent ladies who are members of the Association from attending meetings of the Association". Hence it must be inferred that, in the opinion of the Committee of Council, there are ladies who have the legal status of members of the Association; in which case it would follow as a matter of course that the Committee of Council would have no power to prevent them from attending the meetings. But the admission of women into the Association would involve a radical change in the constitution of that body, such as could not be effected without the general consent of its members. Such consent has certainly never been given. At the meeting which took place in Edinburgh two years ago, some of the members learned for the first time to their great surprise that a lady had been admitted as a member by one of the branches acting entirely on its own responsibility. And a member of that Branch, present at a large gathering of Associates in which the subject was discussed, justified the act by the words of the constitution, in which it was stated that any registered medical practitioner was eligible of membership. But any sound lawyer would, I conceive, inform us that those words must be interpreted according to the meaning which they were understood to bear when the constitution was framed. And, as the idea of any woman being likely to become a registered medical practitioner was far from the minds of the founders and original members of the Association, the words "registered medical practitioner" must be held to be exactly equivalent to the words "male registered medical practitioner", as bearing upon the constitution of the Association. The case is parallel with that of the University of London, where the term "person" used in the charter is universally admitted to mean "male person", so that a new charter is necessary in order to enable the University, however willing, to admit women to examinations and degrees. If this be so, the act of the Branch in admitting a lady to membership was entirely *ultra vires*, and therefore null and void.

In order to ascertain the wishes of the Association generally regarding the admission of women, it was moved at the Edinburgh meeting by Mr. Pemberton, of Birmingham, seconded by Dr. Marshall, of Clifton, and carried by an overwhelming majority, that a voting paper should in the course of the following year be sent to every member, requesting him to reply *aye* or *no* to a query on the subject; and the result was a largely preponderating vote in the negative. The mind of the Association having been thus declared, it was surely the duty of the Council to take the earliest opportunity of writing to the lady in question, apologising for the mistake which the Association had made through one of its Branches in admitting her in a manner which had proved to be entirely invalid, and at the same time returning her any money which she had contributed to our funds. This, however, has plainly not been done. The vote taken with so much trouble and expense to the Association has been allowed to remain a dead letter; and we learn from Dr. Wilson Fox that at the Manchester meeting last autumn a lady not only attended the Section of Medicine, but took part in the discussions. Further than this, the use of the word "ladies" (in the plural) in the resolution of the Committee of Council seems to indicate either that, in spite of the vote, other women have been since admitted in the same illegal manner, or that the Committee anticipate the probability of such

an occurrence. If otherwise, the terms employed by the Committee are certainly most unfortunate, as calculated to create needless uneasiness in the minds of our members.

Let the Committee, then, lose no time in doing what ought to have been done long since, and write to the lady or ladies concerned, in the sense above referred to. Or if they decline the responsibility of immediate action, let them see that the subject be brought before the entire Council at the next annual meeting; and in the meantime let them, if they think it necessary, take legal opinion for the Council's guidance. The affair is of vital importance: for if it be not settled in accordance with the wishes of the majority of our members, I fear it will lead to the disruption of the Association. For my own part, deeply as I should regret to be compelled to sever my connection with a body to which I am personally warmly attached, and which, if conducted on its old basis, is calculated to be in the future, as it has been in the past, of the greatest benefit to our profession, yet I feel as strongly as Dr. Fox does the utter unseemliness and impropriety of having medical topics discussed without restriction in a mixed company of men and women, and I could not consent to belong to any society in which such practices prevailed. On the other hand, believing as I do that the next annual meeting will prove that the due action of the executive body is alone required to clear us from what I cannot help regarding as a disgraceful blot, I would earnestly appeal to Dr. Wilson Fox to withdraw in the meantime his resignation.—I remain, Sir, yours sincerely,

JOSEPH LISTER.

London, Feb. 2nd, 1878.

\* The facts of the case we understand to be these. Early in the year 1873, Mrs. Garrett Anderson, M.D. Paris, L.S.A. London, was elected a member of the British Medical Association and of the Metropolitan Branch, by the Council of that Branch; her paper of application being numerously and influentially signed. On the 14th day of January, 1875, Mrs. Frances Hoggan, M.D. Zurich, L.K.Q.C.P.L., was elected a member of the British Medical Association by the Committee of Council. At the annual meeting of the Association in Edinburgh, at which both ladies were present, attention was called to the subject, and a resolution was carried "That it be an instruction to the Secretary, between now and the next annual meeting, to issue a circular addressed to every member of the Association, requesting an opinion 'Yes or No,' as to the admission of female practitioners to membership." A copy of this resolution, with a request for an answer, was accordingly issued by the General Secretary by post to every member of the Association; and 4,161 answers were received, of which 3,072 were noes and 1,051 ayes. This result was announced at the general meeting in Sheffield. Since the date of the Edinburgh meeting, no ladies have been either proposed or elected members of the Association. Thus the question is narrowed to the relation of the Association to the two ladies mentioned, one of whom has attended and spoken at various meetings of the Branch and of the Association. We cannot but think, with Professor Lister, that means may easily be taken to settle satisfactorily a question which lies within such narrow limits, in the sense of the principle already affirmed by a majority of the members.—ED. B. M. J.

### THE LOST MEDICAL SCHOOL.

SIR,—For some years, as it has appeared to me, Oxford (I speak only of Oxford in this letter, but might speak in much the same sense of Cambridge) has been doing most valuable work in medical education. Year by year, the schools of medicine attached to the large London hospitals have been receiving among their pupils an increasing number of men previously instructed in science at Oxford. And, seeing the stamp of the men, and the extent and quality of their knowledge, London teachers owe great obligation to the teachers, the system, and the influence under whom and which this preparation for purely medical study has been made.

Speaking of advanced education generally, it is no little advantage to teachers and taught that a more or less considerable number of men of good culture and of some years beyond boyhood should be infused among the various classes. No one who has any long experience of London medical schools can be ignorant of a growing improvement in tone and diligence, of a general evidence of aim in study among the pupils. This advance I attribute, in a large degree, to the presence of a number, of an increasing number, of University men. These, as older men who have been long enough emancipated from school to have lost the riotous joy of new freedom, give steadiness to the mixed mass of which they form a part; as trained men, prepared and ready to make practical application of their acquired theoretical knowledge, stimulated, moreover, by some perception of their actual needs and ultimate objects, they give an impulse to progressive study among the

pupils at large; as pupils of teachers of great learning and high purpose, they react upon their new teachers and quicken them in turn.

Seeing this, I have been and am looking forward to the time when views on medical education such as have been long advocated by my own master Mr. John Simon, in one direction, and by the very Oxford teachers who are just now the objects of attack, may assume practical form. The two views put together amount pretty much to the following.

London, with its large hospitals and enormous poor population, offers unlimited opportunity of clinical instruction. Oxford, with admirably arranged museums and laboratories, and large endowments for professors, has almost as unlimited possibilities in the way of general biological instruction. Both would gain, and medical education would be greatly advanced, if each were to take the distinctive part in education suited to its capacity. In neither, at the present time, can there be said to be a complete and satisfactory system of medical education. In London, under the present system, as determined chiefly by the requirements of the several diploma-giving corporations, the strictly preliminary studies are carried on side by side with the clinical studies, very often under the direction of men who ought to be strictly clinical teachers. The student rarely follows his purely biological studies in a thorough way, partly through actual want of time, partly because the atmosphere of clinical work in which he is living distracts and draws him on prematurely to the technical applications which are more fascinating to most minds. Zoology and botany receive little attention, save from a few aspirants for degrees at the University of London; the time allotted to chemistry is altogether inadequate; and physiology is for the most part taught by men engaged in clinical work and private practice, by men who, if they have the knowledge and appliances, have not time to use them effectively in teaching.

As regards Oxford, it is evident that, if anyone should hope, as things stand, to get a complete and thorough medical education there, he would be doomed to disappointment. But, if the work and the avowed objects of the Oxford biological teachers be looked at in a broad and statesmanlike way, there is no ground for regret in this disappointment. Oxford, being content to teach well and thoroughly what she can teach in such manner, and to leave London to supply what she herself cannot; being content to develop to the full her resources of biological instruction, and to let the men she has trained seek their clinical instruction in the splendid field offered by the largest city in the world, will survive the attacks now made on her, and enormously advance the study of medicine in England. In her large and admirably arranged museums and laboratories, under teachers who can devote their whole day to their teaching and its subjects, many a medical student of the near future will be able to pursue, undistracted and unhurried, his preliminary biological studies; and afterwards he can come, as men pass from school to college, to London, to find there the material of purely medical study and teachers no longer embarrassed by the duty of imparting preliminary instruction. Here, as may be hoped, he will study at once the pathological aspect of physiology, the surgical and medical anatomy of man, the processes of disease, the treatment of the sick. In this relation, the total existing appliances of the London schools will be none too large for the needs of comprehensive, though purely medical, study. It may be said that there are good schools of biological science in London, and that they may also take up the work of preparation. This I cheerfully recognise; nay, most hopefully; for, while I am chiefly speaking of Oxford as a type, I am keeping in view the necessity of the preparatory work being carried on in many places, but always under such conditions of separation from the applied work as Oxford presents.

It has been urged that Oxford, having an infirmary with a staff of medical officers and a considerable population, is capable of being a school of clinical medicine, the experience of German universities being cited in favour of the argument. But, from the point of view here taken, the wisdom of the Regius Professor in not attempting to make a small medical school at the expense of the great School of Biology which he and his associates are fostering, commends itself to me. Others have elsewhere pointed out that the famous schools of clinical teaching springing up in the comparatively small university towns of Germany are mostly the creation of individuals, and wane when their great lights are quenched. Furthermore, the distances between centres are mostly great in Germany; and that, nevertheless, men go from school to school to complete their education. Oxford, with her two or three hundred beds and population of a few tens of thousands, lies, in regard of distance and of clinical opportunities, under the shadow of London, with her millions of population. The clinical part of education can be given so much more fully and completely by London (only two hours' journey distant), that Oxford is wise in refraining from competition, and is equally wise in refraining from spoiling the work pro-

perly falling within her scope by the forced introduction of work of another kind.

These considerations are not set forth without the consciousness that they have a bearing upon the whole question of medical education. But the time has come, and perhaps the occasion, when the question of medical education may be once more reviewed rather from the side of teaching than from the side of examining, which appears to me to absorb a most disproportionate attention. It is clear that such a division of work as is here contemplated, with some attempt at completeness in both departments, will involve a large extension of the recognised period of medical study. So be it. The total period of study is at present far too short, chiefly because a preparatory stage has been cut off by the regulations of recent date. As long back as I have had any opportunity of advising young men on the commencement of medical study, I have advised them to spend at least a year—if possible, more—between leaving school and going to a hospital in learning something of pharmacy, chemistry, botany, and the rudiments of anatomy. Since the much-to-be-lamented abolition of apprenticeships, this sort of intermediate training has been doubly needed. And, if the present discussion about the "Lost Medical School" shall serve to draw attention to the necessity for schools of scientific training intermediate between school life and hospital study, I am sure that the far-seeing men who are bent on making Oxford a great biological school of the kind will not complain.

The regulations of the University of London illustrate the want of harmony between the present method of education and the requirements of a good degree examination. Although the subjects included under the term "preliminary science" are all taught at several of the London hospital schools, "preliminary science" has been separated from the properly medical examinations, and candidates are advised to pass the examination in that subject, if possible, before going to hospitals. It is certain that, if they do not, students have to neglect most of the work properly belonging to their first year at a hospital. In the fact that the examinations at the University of London are held at times which fit in no way with the general order of study in the hospital schools, and in the fact that the examinations are so arranged that students entering for them must actually break off from the ordinary classes, is a strong indication that the Senate considers the present routine of medical education too short and imperfect to be the basis of the examination for its degrees.

The views here advocated are by no means new or original, but are once more brought to the front, in the hope that a retrogressive policy may not be forced upon the University of Oxford.

It is with medicine as with seamanship; both require long training, early and late; in both, science and practice are appropriately taught in different places. Because London has museums and schools of naval architecture, and every appliance for teaching the theory of seamanship, it does not follow that men may be trained to navigation, to sail ships in storms, on the Thames. A man is made a sailor only by going to sea. In medicine, London offers, so to speak, the sea on which men scientifically taught at Oxford or elsewhere may become masters of their art.—I am, sir, your obedient servant,

WILLIAM M. ORD, Dean of the Medical School  
of St. Thomas's Hospital.

London, February 4th, 1878.

### THE PRESENT INFLUENCE OF OXFORD UPON MEDICAL EDUCATION.

SIR,—It is naturally a somewhat delicate matter for medical graduates of Oxford to come forward and state all that they know and think respecting the conditions of medical education now existing in their own University.

While the questions bearing upon this large and debatable subject remain open, it may not, perhaps, be unseemly for one who has had many opportunities for observing the influence of Oxford training upon the men who pass from that University to the larger medical spheres of London and Edinburgh, to afford his testimony to that influence.

In the first place, I think it is important to recognise, as Dr. Chambers has pointed out, that there is, properly speaking, no medical school in Oxford, nothing at all corresponding to a Faculty as understood in the Scottish and Continental Universities. In default of this, candidates for the B.M. degree present themselves at large recognised medical schools after securing as many special advantages as are within reach in their University.

First, I wish to enumerate these advantages as they exist; and, secondly, to state my experience for the last fifteen years of the in-

fluence they have exerted upon many of the candidates who have enjoyed them.

It is found, for the most part, that Oxford men who purpose following medicine as a profession pass out through the Natural Science School to their B.A. degree. This, in itself, secures an early acquaintance with several subjects of prime importance in relation to early medical training. Thus, a study of Botany, Chemistry, Natural History, Physics, Comparative Anatomy and Physiology, or of some of these subjects, is commenced in the second year of the undergraduates' course, and a sound basis is thus laid in direct relation to future and more exact study of some of these sciences. Surely, nothing can be better than such a course as this. It simply provides the best preliminary curriculum in the best possible manner for the medical student proper. And when to this special training are added the required attainments in *literæ humaniores*, and the invaluable culture and refinements of academic life, as barely realised anywhere but in the old English Universities, we find, in my opinion, the highest type of candidate for the special study of the medical art.

Such, at all events, is my experience of the men who present themselves from Oxford at the great medical schools. They come, it is true, with little or no practical knowledge, and are, as Dr. Payne points out, much behind the average medical student in this respect. But they come, for the most part, with minds already well-trained, eager to learn, and prepared to acquire and make their own all that has to be taught; and it is simply incontrovertible that they very speedily reach the level of, and in many instances surpass, the rank and file of ordinary hospital pupils.

While I bear this testimony, I am aware that this is not the point now at issue and under discussion in your columns, and I leave to others better conversant with the University to express their opinions respecting it. I myself could never imagine Oxford as a fully equipped medical centre, and have been content to regard its limited number of medical graduates somewhat in the light of a *corps d'élite* who have given a tone and character to the profession wherever they have established themselves.

With the late Sir Henry Holland, I have also believed that "there must always be an aristocracy in every profession". This much, however, I may say, that, with the materials at their disposal, it has appeared to me that the present medical professors have done splendid work, and have well maintained the character of their chairs. As an outsider, I can also testify to the facilities afforded me for study by one of them some years ago.

Whether or not, by more subdivision of their labours, by incorporating the Scientific Fellows of the separate Colleges into a systematic teaching body, working under the professoriate, a more thorough training might be given in various branches of Anatomy and Physiology, I am unable to state. Possibly something beneficial may be achieved in this direction, leaving the larger question of establishing a complete medical faculty for further and more mature consideration.—I have the honour to be, sir, your obedient servant, M.D. EDIN.

London, January 30th, 1878.

### PHYSICIANS' FEES.

SIR,—Twenty-six letters and a leading article in the *Times* on "Medical Charges", and as much writing, if not by so many writers, in our *BRITISH MEDICAL JOURNAL* on "Physicians' Fees", ought to produce some fruit. I think it might produce good fruit, if the respective writers would give their names, with a view to further conference. My own sentiments are most in accord with those in your pages who signed themselves "F.R.C.P." and "F.R.C.S."; but I do not think their suggestions sufficiently deep. The root of the matter is, that "consultations" ought to be improved in character. The old-fashioned mode of conducting a consultation is not suitable to the present condition of medical science. Improve the article, and the improvement in price will follow.—I am, yours faithfully,

Derby, Jan. 29th, 1878. WILLIAM OGLE, M.D., F.R.C.P.

P.S.—If the writers of the several letters, or any who agree with them, will favour me (in confidence) with their names, I will arrange, if practicable, for some further action on the subject.—W. O.

SIR,—Much has been written upon this subject of late, but one important point has not been touched upon, namely, the duty of the consultant to the consultee. It appears to me that, when a patient is sent to a consultant for an opinion by a general practitioner, the prescription and any hints as to treatment ought to be forwarded to the regular attendant, and not given to the patient; for it is no consultation if the consultant gives the prescription to the patient, tells him to

take it to some pet chemist, and to come to him again after a time. I have sent patients to men of standing in London, and requested them to send me their opinion of the case, together with their prescription, but from their acting as above have lost hold of my patient for a time. In the law things are managed better, and the Q.C. only gives his opinion through the solicitor sending the case to him.—I am, etc.,  
February 4th, 1878. L.

### EXTENSION IN HIP-JOINT DISEASE.

SIR,—In his letter in the BRITISH MEDICAL JOURNAL of January 26th, Mr. T. Holmes disputes the claim of the American surgeons to priority in the use of weight-extension as a remedy for acute pain in hip-joint disease, and observes: "I have used and seen used this method of treatment for, I should say, at least twenty-five years. I claim no originality in the method, for it was certainly used by my predecessor at the Hospital for Sick Children, Mr. Athol Johnstone; and in Mr. Marsh's paper, to which Mr. Adams gives a reference, there is a quotation from Sir B. Brodie's first edition very clearly recommending it." I trust you will allow me to make the following remarks in reply.

The quotation in Mr. Marsh's paper (*St. Bartholomew's Hospital Reports*, vol. ii, page 153. London, 1866), above referred to, is as follows. Speaking of weight-extension, Mr. Marsh observes: "This appliance was recommended by Sir Benjamin Brodie in the first edition of his well-known work on *Diseases of the Joints* in the following terms: 'I will not say that the effect of such a continuance of extension (by the weight) is to prevent the shortening of the limb altogether, but I am satisfied that it will, in many instances, render this less than it would have been otherwise; at the same time preventing, or very much diminishing, the excessive aggravation of the patient's suffering, with which shortening of the limb is usually accompanied.'"

In the fifth edition of Sir Benjamin Brodie's work on *Diseases of Joints*, published in the year 1850, *i.e.*, thirty-two years after the first edition, the only passage I can find referring to the use of weight extension in joint-diseases is the following, at page 139. "In some cases where, the disease being in an advanced stage, there seemed reason to apprehend a displacement of the head of the femur with a retraction of the limb, I have endeavoured to prevent it by the application of a moderate constant extending force. For this purpose, a leather strap was applied above the condyles of the femur, having a string attached to it, passing over a pulley fixed, at a moderate height, to the lower end of the bedstead, and supporting a light weight; the pelvis being at the same time fixed by a strap to the middle or upper end of the bedstead. This, in some instances, seemed to relieve pain; and I am inclined to think that it was useful otherwise, by counteracting the muscles, which tended to draw the limb upwards. However, it almost always happened that something occurred to prevent the experiment being fully and fairly tried; and all that I can venture to say respecting it is, that it may be worth while, in certain cases, to give this mode of treatment a further trial."

In the collected works of Sir Benjamin Brodie, by Mr. Charles Hawkins, published in 1865 (vol. ii, page 151), the same paragraph appears, in precisely the same words, clearly showing that the subject had not at any time further attracted the attention of Sir Benjamin Brodie.

It is quite clear, from the above quotations, that Sir Benjamin Brodie did not employ weight-extension for the relief of acute pain in hip-joint disease, but with the view of preventing contraction and dislocation. It appears remarkable, however, that, when the weight-extension "in some instances seemed to relieve pain", it never occurred to such an acute observer as Sir B. Brodie to employ the same means in the cases of excruciating pain, with involuntary startings of the limbs, etc., described in his work—as in Cases Nos. 14, 31, etc.—cases in which, according to late experience, it would probably have been eminently successful.

Sir Benjamin Brodie (*op. cit.*) speaks of the impossibility of applying any mechanical means to ensure absolute rest in acute inflammation of a joint, as the pressure of a bandage cannot be borne; and observes: "The pain which the patient experiences on every movement of the limb is a sufficient guarantee that he will use his best endeavours to keep it in a state of repose. These may, however, be assisted by prescribing the maintenance of the recumbent posture, and by laying the affected joint on a waterproof pillow, partially distended with air or water, which, by bulging forward on each side, will give sufficient lateral support to counteract, in some degree at least, the ill effects produced by an involuntary starting of the limb." This, together with local and general antiphlogistic means, was the treatment adopted by Sir Benjamin Brodie in cases of acute diseases of the joints; and I do

not find any mention of the application of weight-extension in the treatment of any of the numerous cases recorded in Sir B. Brodie's works.

Mr. Holmes does not claim more for himself, and his predecessor Mr. Athol Johnstone, than to have employed weight-extension during the progress of hip-joint disease; without any special reference to its power of relieving acute pain, and thus superseding the necessity for the severe antiphlogistic treatment of our predecessors. This, which we must admit to have been a great discovery, undoubtedly belongs to the American surgeons; and the first published account of the practice, and its explanation of relieving pain by overcoming reflex muscular contraction, and thus preventing interarticular pressure, is, so far as I am aware, that given by Dr. Davis of New York, in his work *On Conservative Surgery*, 1855, alluded to in my paper read at the Manchester meeting, and published in the JOURNAL of January 5 h.

Whilst Sir Benjamin Brodie thought weight-extension might be useful in preventing contractions and dislocations, we know that it was employed more than thirty years ago for the straightening of contracted joints. In my work on *Club Foot*, second edition, page 401, the case is described of a gentleman who consulted me, in 1852, for contraction in both knees, and who had been subjected to a treatment by weight-extension ten years previously, *i.e.*, thirty-five years from the present time; a weight of twenty-five pounds being applied to each leg.

I employed weight-extension successfully in a case of contraction after hip-joint disease, in the year 1849, in a young gentleman, in whose case the late Mr. J. H. Green recommended that weight-extension should be tried.—I am, sir, yours, etc.,  
WM. ADAMS.

Henrietta Street, Cavendish Square, January 29th, 1878.

### SAYRE'S TREATMENT OF SPINAL DISEASE.

SIR,—The time for discussion on Mr. Berkeley Hill's interesting spinal cases treated on Dr. Sayre's plan, at last Friday's meeting of the Clinical Society, was so limited that I had no opportunity of informing the members present, that this so-called newly introduced method of suspension by the gallows has been largely employed, for many years past, in several orthopaedic institutions on the Continent; and that I saw last spring nearly the same kind of apparatus used by Dr. Klopsch, Professor of Surgery at Breslau in Prussia. Here a strong horizontal beam is supported at its middle on a vertical mast fixed in the ground, and from the two extremities of the former depend exactly the same kind of gallows as is attached to the apex of Dr. Sayre's tripod. The patient's head having been fixed in the way now well known here, the cord is shortened till the toes can only just touch the ground. The patient is now told to walk round and round, the horizontal beam being made to turn on a pivot. There are usually two or three cross beams, so I have seen as many as six patients walking round simultaneously, as best they could, on tiptoes, while their spines were being extended by the weight of their bodies. Complete suspension in the air is also employed very often. Even the shoulder-loops are quite identical with those now said to have been invented by Dr. Sayre. I saw a similar apparatus and treatment at the Orthopaedic Institution of Dr. Schilbach, at Leipzig. This gentleman is a *privat docent* of, and has an orthopaedic out-patient's department in connection with, the University of Leipzig. It is a curious fact that, in Germany, the gallows is called Glisson's swing (*Glissonische Schwebel*), after Francis Glisson, an English physician, who wrote a book *De Rachitide*, a second edition of which appeared in London in 1660. He gives, at page 368, a description of the swing, with an illustration, and explains the principle on which it is used. I have no wish to depreciate the great debt of gratitude we owe to Dr. Sayre for the introduction of the plaster of Paris bandage for spinal disease, especially Pott's disease; but I do not think it is quite fair that no acknowledgment has been made of the real inventor of the suspender, or of the fact of its having been long in common use in Germany.—I remain, yours obediently,

BERNARD ROTH, M.D., M.R.C.S. Eng.

48, Wimpole Street, W.

## MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Friday, February 1st, 1878.

*Hydrophobia*.—In answer to Lord C. Hamilton, the CHANCELLOR of the EXCHEQUER said that the attention of everyone had been directed to the increase of hydrophobia and to the number of stray and dangerous dogs, and that the Government were considering the subject with a view to legislation.

Monday, February 4th.

*Medical Officers of Health*.—Colonel NACHTEN asked the President

of the Local Government Board whether he had considered the desirability, with a view to the better carrying out of the Public Health Act, especially with regard to the suppression of nuisances, of making it compulsory to appoint the medical officers of health in all cases for unions or other large areas, instead of, as is now sometimes the case, for parishes only.—Mr. SCLATER-BODDIE said he did not intend to propose any change in the law on that subject; but the Local Government Board had always encouraged a combination of local authorities in respect to the appointment of these officers, and it would continue to do so.

## MILITARY AND NAVAL MEDICAL SERVICES.

**ARMY MEDICAL SERVICE.**—List of army medical candidates, who were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School, Netley, February 1878.

	Marks.		Marks.

## PUBLIC HEALTH

AND

## POOR-LAW MEDICAL SERVICES.

### ACTION AGAINST A MEDICAL OFFICER OF HEALTH.

SIR,—In your comments upon the County Court action lately brought against me and the sub-inspector to recover the value of some herrings which we were alleged to have illegally seized, you state "the defendants were represented by Mr. Proud, but whether or not he was clerk to the local authority is not stated, and we do not, therefore, know whether or not Mr. Manson was properly supported by his board". Kindly permit me to explain that Mr. Proud is not the clerk to the local authority, but was employed by them; and further, that I am happy to state that I have always received every consideration and all necessary support from the board. With reference to the risk at which medical officers of health carry on their duties, I may mention that I was advised that there was a statutory defence to the action brought against me: in fact, a plea that, as I was acting in my official capacity, no action would lie against me. However, it was much better for the case to be tried on its merits than to have even the appearance of shirking inquiry. The plaintiff supported his case by witnesses who said they had eaten some of the fish. I am afraid some people will eat anything; and, if such evidence be of any weight, a conviction for selling unsound food will be difficult to obtain.—I am, sir, your obedient servant,  
R. T. MANSON, Medical Officer of Health  
for No. 1 District, Auckland Union Sanitary Authority.  
Howden-le-Wear, February 4th, 1878.

### PUBLIC HEALTH MEDICAL APPOINTMENTS.

FRANK, D. Edgar, L.K.Q.C.P.I., appointed Medical Officer of Health for the Brownhills (Staffordshire) Local Board District.

### POOR-LAW MEDICAL APPOINTMENTS.

ELSON, Frederic, L.R.C.P., appointed Medical Officer and Public Vaccinator to the Whitwell District of the Workop Union, *vice* H. E. Walker, M.R.C.S., resigned.

## MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members on January 31st, 1878.

Cottle, Ernest Wyndham, M.B.Oxford, 3, Savile Row  
Duncan, James Matthews, M.D.Aberd., 71, Brook Street

### MEDICAL VACANCIES.

THE following vacancies are announced:—  
BRECON INFIRMARY—Resident House-Surgeon. Salary, £100 per annum, with apartments, attendance, fire, and lights. Applications to be made on or before the 11th instant.  
CASTLEBLAYNEY UNION—Medical Officer to Dispensary District. Salary, £125 per annum, exclusive of emoluments as Sanitary Officer, Registration and Vaccination Fees. Applications to the 14th instant.  
CLIFDEN UNION—Medical Officer for the District comprising the Islands of Inishboffin and Shark. Salary, £90 per annum, exclusive of Registration and Vaccination Fees. Applications to the 13th instant.  
DENTAL HOSPITAL OF LONDON—Dental Surgeon. Applications to be made on or before the 13th instant.  
GENERAL INFIRMARY, Hertford—Medical Resident and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before March 6th.  
GENERAL INFIRMARY, Northampton—Surgeon. Applications to be made on or before the 27th instant.  
HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester—Resident Medical Officer. Salary, £100 per annum, with board, residence, etc. Applications to be made on or before the 14th instant.  
HOSPITAL FOR WOMEN, Soho Square—House-Physician. Applications to be made on or before 12th instant.  
IPSWICH BOROUGH LUNATIC ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance.  
LINCOLN LUNATIC HOSPITAL—Resident Medical Superintendent. Salary, £150 per annum, with board, lodging, and washing. Applications to be made on or before the 16th instant.  
LIVERPOOL ROYAL SOUTHERN HOSPITAL—Two Honorary Surgeons. Election in February. For particulars, apply to Honorary Treasurer.  
METROPOLITAN FREE HOSPITAL—Assistant Physician. Applications to be made on or before the 12th instant.  
NARBERTH UNION—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.  
NORTHAMPTON GENERAL INFIRMARY—Physician. Applications to be made on or before the 20th instant.  
QUEEN'S UNIVERSITY IN IRELAND—Examiners for 1878 in the following subjects, at the salaries stated. Medicine, £100; Surgery, £100; Midwifery, £75; Materia Medica, £75; Medical Jurisprudence, £75. Applications to be addressed to the Secretary, at Dublin Castle, up to the 15th instant.  
ST. GEORGE'S HOSPITAL—Surgeon and Assistant-Surgeon. Applications to be made on or before the 13th instant.  
TOBERMURRY UNION—Medical Officer of Coolaney Dispensary District. Salary, £120 yearly, with Registration and Vaccination Fees. Applications to the 11th instant.  
WESTMINSTER HOSPITAL—Aural Surgeon and Assistant Surgeon. Applications to be made on or before the 26th instant.  
WESTERN GENERAL DISPENSARY—Honorary Surgeon. Applications to be made on or before the 11th instant.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\*PAUL, Frank T., M.B., MA., appointed Pathologist to the Liverpool Royal Infirmary, *vice* \*Rushton Parker, M.B., appointed Assistant-Surgeon.  
\*HAGON, W. E., L.R.C.P., appointed Assistant Medical Officer to the Central London District Infirmary at Highbury.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

#### BIRTHS.

FREEER.—On January 4th, at The Lindens, Lozells Road, Birmingham, the wife of \*Edward L. Freer, M.R.C.S. Eng., of a daughter.  
SKRIMSHIRE.—On January 30th, the wife of \*Charles Parnham Skrimshire, M.R.C.S. Eng., of Clydach Villa, near Abergavenny, of a son.

PRESENTATION.—Mr. Caskie of Largs was recently presented with a massive tea and coffee service, and silver, and a purse of sovereigns, by a number of the residents of Inverkip, Wemyss Bay, and Skelmorlie, at a public entertainment given in his honour.

A CENTENARIAN.—There is at present an old lady residing in Lower Crumpsall, who has attained the age of 103 years. Her name is Jane Pinkerton, and she resides with her daughter, who is 72. She was born at Paisley in June 1774. She went to the north of Ireland, and married in 1798. About thirty-four years ago her husband died.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Dr. Kelburne King (Hull). "A Case of Ligature of Carotid and Subclavian Arteries for Aneurism of Arteria Innominate, and Aorta"; Mr. Balmano Squire, "Two Cases of Flat Vascular Nævus successfully treated by repeated Linear Scarifications"; Dr. Althaus, "On Diseases of the Anterior Cornua of the Spinal Cord".

**TUESDAY.**—Royal Medical and Chirurgical Society, 8 P.M.: Ballot, 8.30 P.M.: Dr. Poore, "Analyses of Seventy-five Cases of Writers' Cramp"; Dr. Broadbent, "On a Case of Amnesia".

**WEDNESDAY.**—Hunterian Society, 7.30 P.M.: Annual Meeting for Election of Officers, 8 P.M.: Annual Oration by P. L. Burchell, M.B.

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**SIR,**—Can you inform me if there is an English translation of Bouchut's *Traité des Maladies des Enfants*? and oblige, yours faithfully,

REGLAND.

\*. \* We are not aware that there is one.

## MEDICAL EDUCATION OF WOMEN.

**SIR,**—Dr. Wilson Fox has, in my opinion, opened a question worthy of serious and dispassionate consideration by the British Medical Association. I think few will deny that the loss of such a member to the Association is of more importance than that of any number of half-informed young ladies. When I say half-informed, I speak advisedly, for I could not conceive any English gentleman imparting, or any English lady receiving or studying, the entire curriculum of medicine and surgery. But independently of this narrower view, there is the wider one, whether the British Medical Association, by opening its doors to women, does not thereby encourage them in prosecuting the study of medicine, with its always possible results. It would be out of place here to enter on the effects of such study on the virgin mind. One result alone—that a maiden should acquire knowledge that a matron should not possess—should be sufficient to cause every father and brother to oppose such a perversion of education. We have enough to contend with, in shielding our maidens from the vile influences of "Priests in Confessional" and books of the Besant and Bradlaugh order, without aiding them in studies unbefitting their sex.—I am, sir, yours faithfully,

R. EATON POWER.

Dartmoor, February 1878.

**AN** article to which our attention has been called in the *Dublin Mail* of the 30th ultimo, upon the Dublin Orthopaedic Hospital, is, in our opinion, open to very grave objections. We trust that the medical gentlemen whose names are therein mentioned had no complicity with the publication of the article in question; and in any case it is to be regretted that facility should have been afforded for the publication of an article so closely allied to an advertisement, and the particular powers there attributed to the medical officers. Such publications are injurious to the character of the profession, and call for general condemnation.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a Post Office.

## SUICIDE OF A STUDENT AT GUY'S HOSPITAL.

**SIR,**—The suicide of one of the students at Guy's Hospital has caused sincere regret. It is not my purpose to attribute blame to any one, or to try to elucidate the real cause of this sad occurrence. Such a task would not only be difficult, but, I am inclined to think, unjustifiable. At the same time, the public have been led to suppose, from an account which appeared in one or two of the daily papers, that this suicide was due to the disappointment and chagrin caused by the refusal of the authorities to allow the student in question to present himself at the College of Surgeons. Be this so or not, I think much good may arise if the present practice in regard to the signing of schedules at Guy's and some other medical schools is reconsidered. Under the existing arrangements, those who are responsible for these matters delay giving an answer to the majority of students until the last day for sending in the papers to the Royal College of Surgeons. In some instances, this practice is carried to such excess that students have been known to be refused admission to an examination, because they have not been able to get their schedules from the medical school authorities until late in the afternoon. Students are kept in doubt under this system until the very last moment, and then, if the answer be unfavourable, the reaction after the excitement of a prolonged suspense is likely to do much mischief. If the schedules are signed, the evil is only a degree less, for by the time the student has been to the College and made the necessary arrangements with the authorities there, he is practically fit for little. Just let your readers imagine the effect of a student waiting, waiting, waiting for an answer from his teacher from ten o'clock till late in the afternoon each day, and day by day during the last three or four days, before an examination! His precious time is wasted; for how can he pretend to read with this load of anxiety on his shoulders? His temper is ruffled, and his nerves become unstrung. Under such circumstances, the wonder is that many of the students pass at all. If the authorities would only place themselves in the position of the students under circumstances similar to those I describe, a new rule would soon be made. The reform needed is, that the classes for the second College examination should commence quite two months before each examination, and the decision of the lecturer should be announced and a list of those men who are considered fit to be admitted to the examination posted in the hall at least a week before the last day for sending in names to the College of Surgeons. If this alteration were made in the direction I suggest, I am convinced that in the future the probability of a repetition of the sad event recently enacted at Guy's Hospital would be considerably lessened. It is no excuse to say that the authorities are anxious to let as many men up as possible, and hence the necessity of the present system; because, if a student be not sufficiently advanced a week before an examination, for his own sake and in the interest of the school he should be kept back.

Hoping you will exert your influence to put an end to a system which has led to great evils in the past, for by its means teachers are made unpopular, parents are dissatisfied, and students are rendered less able to meet the examiners with confidence and nerve.—I am, etc.,

A FOURTH YEAR'S STUDENT.

**T. M.**—Under the circumstances, we think the course permissible, proper care being of course taken that the stated limits are not overstepped.

## AN APPEAL.

**SIR,**—I venture to appeal to your readers on behalf of the family of Mr. J. C. White late senior house-surgeon to the Ardwick and Ancoats Dispensary, who was tried, convicted, and sentenced to five years' penal servitude at the last Manchester Assizes, for attempting to procure abortion. However indignant we may feel that a member of our profession should have been guilty of such an offence, we surely must all sympathise with the wife and children, who are thus suddenly left, through no fault of their own, in a state of utter destitution. A subscription-list has been opened, with a view to affording temporary assistance to Mrs. White until she is able to obtain some employment. The Rev. John Watson, Rector of St. Jude's Mill Street, Ancoats, Mr. Cullingworth, and myself, form a committee to receive contributions and to see that the funds are properly applied. We shall be greatly obliged to any friends who will help us. Post Office orders may be made payable to me at the Branch Office, Downing Street, Manchester.—I am, sir, yours faithfully,

T. N. DEAN, Consulting Surgeon to the Ardwick and Ancoats Dispensary.

37, Shakespeare Street, Ardwick, Manchester, February 6th, 1878.

**P.S.**—Without wishing in the least degree to palliate the crime, I may mention incidentally that the young woman has received no injury, and that at the time of the trial she was still pregnant of a living fetus. I may also state that there was no evidence to show that White had any personal reasons for trying to induce abortion. He appears to have had no other object in view than that of helping a married acquaintance to escape the consequences of an improper intimacy with his servant.

T. N. D.

"A SUFFERER" should personally consult one or more competent members of the medical profession.

## BOOKS OF REFERENCE.

**SIR,**—To a "Member" asking for two good practical reference books, I would recommend Flint's *Practice of Medicine* (Lea, Philadelphia) and Murphy's *Midwifery*.—Your obedient servant,  
Wm. VANDREY LUSH, M.D.  
Weymouth, January 30th, 1878.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### INSURANCE INQUIRIES.

SIR,—Allow me to inquire through your columns what the profession ought to do, or does, in regard to a new system of inquiries made by insurance offices, especially the smaller ones, as to the nature and duration of the fatal disease of claimants—not only such as we return to the Registrar-General, but also whether there were any other disease, "its name and history"? "If you do not know how long the fatal disease existed, how long do you think it did?" Also, "whether you have any suspicion that irregular habits had anything to do with the illness, or with its fatal termination". As a consultee, it rarely happens that I am called on to sign certificates myself, but they are sent on to me from the medical man in attendance whom I have met, and, looking upon them as catch questions, I have myself ignored, and have advised others to ignore them; merely to state what was the fatal disease, and the duration of the second or final cause of death; also to make a note of the office requiring such answer. Suppose the doctor dates a diseased heart from an attack of acute rheumatism twenty years before, and the company's own referee has overlooked it, his own doctor, never consulted about insurance, is forced into the position of instigating the dispute of a policy. Again, about intemperate habits. To sign an open certificate that they have hastened death, or that you suspect so, when perhaps the drinking has been secret, and indignantly denied by patient and friends, when also a few months before some office has taken the life without inquiry as a first-class one—to do this would be, I hold, simply suicidal on the part of a doctor; to ask it, ought, I think, to deprive any office doing so of any medical support or recommendation.—Your obedient servant,  
Leicester, February 3rd, 1878.

JOHN BARCLAY, M.D., F.R.C.P.

#### DEPORTED PAUPERS: THE CASE OF MICHAEL KENNY.

SIR,—In an article headed "Deported Paupers", in the JOURNAL of January 10th, you give an account of the circumstances connected with the death of a pauper named Michael Kenny, taken from the Liverpool Workhouse on November 16th, 1877, for removal to Ireland, which is erroneous in several important details. As I am the medical officer concerned in the case, and your strictures reflect strongly on my conduct in consenting to his removal, I hope you will allow me space to put the matter before you in its proper aspect.

Michael Kenny, aged 35, was admitted to the Liverpool Parish Infirmary on October 10th, 1877, and, on examination, was found to be suffering from tubercular deposit to a limited extent in both lungs. During the time he was in hospital he was not confined to bed, nor had he an acute symptom during his stay; on the contrary, he was actively engaged in assisting the trained nurse in carrying food, medicines, etc., and this of his own accord. He was again examined, at the request of the removal authorities, on November 10th; and there being no action in the tubercular deposit and his state being the same as on admission, I signed the order for his removal. The night of his removal was neither wet nor stormy, as proved by the evidence of the removal officer and the log of the ship. He was a steerage and not a deck passenger; and if he exposed himself during the passage it was his own act, for it was proved that the ship affords covered space for about one hundred and fifty steerage passengers, and there were only about forty or fifty on this particular night. With regard to the removal, the words of the coroner, Dr. White, are as follow: "They" (the removal officers) "appear to have done so with humanity." When leaving the Liverpool Workhouse, he had flannels (singlet and drawers) given to him, and was warmly clad. On arriving at the South Dublin Union, he was asked by the authorities there if he had any complaint to make, and answered "No." He then took his own discharge, and nothing further was heard of him until November 21st, when he was admitted to the South Dublin Union, "suffering from bronchitis." You will thus see that he was not "so ill that he was at once removed to the workhouse infirmary." There is an interval of four clear days, during which there is nothing known as to his actions or whereabouts. On his admission to the Dublin Union, it was proved that he was poorly and insufficiently clothed. The presumption is, that he pawned his clothes for food or drink, or both.

In your article you speak of his "weak and wasted frame": now, when he left this, he was neither weak nor wasted, but in a fairly nourished condition, and fit to undertake the journey. As to his being "unfit to be removed to the healthy wards" while in the Liverpool workhouse, this was explained at the inquest, but not reported in the newspapers. It is a rule with us in this workhouse to admit all paupers suffering from phthisis, no matter how incipient the stage, into the wards of the hospital; so that, not being free from disease, he was unfit to be removed to the healthy wards. There was not sufficient disease to interfere with his removal to Ireland; and had he asked for it, I would have given him his discharge to follow his occupation, that of a waiter.

As to Kenny's condition from the 21st November until about a fortnight before his death, when he came under the charge of Dr. Nicholls, there was no evidence. I think it is conclusively shown by the above facts that the deceased did not suffer by the act of removal. While in the Liverpool workhouse, his diet differed from that of the healthy inmates only in the addition of a pint of milk daily.—I am, sir, yours truly,  
WILLIAM IRVINE.

#### CLIMATE AND CIRCULATION.

SIR,—In the quarterly report on the health of Dublin, I see there are one hundred deaths set down to circulatory diseases. The proportion seems high, and tends to heighten my suspicion that the natives of comparatively mild western climates have slighter hearts, arteries, and veins than people of countries where the vicissitudes of temperature are more sudden and pronounced. Can any of your readers give instances from personal knowledge on the subject? My own experience of a weak heart is, that it gets on much better near the west coast of England or Wales than anywhere inland or eastward. I should much like to know if there are any medical statistics published bearing on this point.—Yours faithfully,  
January, 1878.

C. L. B.

MR. GARNER (Birmingham).—We believe that arrangements will probably be made before the end of the year for carrying out the object which Mr. Garner suggests. His letter has been handed to the General Secretary for the information of the JOURNAL and Finance Committee.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### MEDICAL REPORTS ON OFFICIAL EMPLOYERS.

SIR,—I should be glad of your opinion on the following case. A. B. has had under his care for some years a patient who is clerk in an insurance office. On the patient's return to work after a temporary absence from ill health, certified to by A. B., he is seen, at the request of the authorities, by C. D., the medical officer of the institution. C. D. writes to A. B. in the following terms: "I should be much obliged if you can give me any particulars you can as to the state of health of Mr. —, a clerk in the — Office. As medical officer to that office, I have been requested to see Mr. — in reference to the state of his health and fitness for work, and he informs me that he has been for some years under your care. I shall be particularly obliged for your opinion as to his health previous to his contracting the disease from which he is now suffering."

A. B. replies, and sends a report and his opinion of the patient's state of health. He then asks to whom he is to look for his fee, adding that as the office is to benefit by the information, he thinks they should pay it (not the patient). In reply, C. D. offers to send the fee himself! adding, "At the same time I would mention that the questions I asked were for my own information—as one medical man from another, and as I am in the habit of sending and receiving on the terms that are usual between members of the profession."

A. B. of course declines to accept anything from C. D., but protests against the view C. D. takes, pointing out that the information is only valuable to the office, and not in the least to C. D. personally. I should be glad to know what the ethical rule is in similar cases.—Yours faithfully,  
HENRY W. KIALMARK.

66, Princes Square, January 30th, 1878.

\* The office ought to pay the fee; and C. D. is not, we think, justified in asking the desired information from A. B. on any other terms.

We are indebted to correspondents for the following periodicals, containing news reports, and other matters of medical interest:—The Birmingham Daily Post; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Derbyshire Courier; The Auckland Times and Herald; The Auckland Chronicle; The Western Mercury; The Daily Courier; The Lincoln Gazette; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Masbro' Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Richmond and Ripon Chronicle; The Cambridge Independent; The Madras Mail; The Ashton Reporter; Saunders' News Letter; The Western Mail; The Bath Chronicle; The Bolton Chronicle; The Lincolnshire Chronicle; The Chippenham Chronicle; etc.

# AN ADDRESS ON SOME POINTS OF SCIENCE AND PRACTICE CONCERNING CANCER:

*Delivered at the Annual Inaugural Meeting of the Midland Medical Society at Birmingham, on November 9th, 1877.*

By JOHN SIMON, C.B., D.C.L., F.R.S.,

Consulting-Surgeon to St. Thomas's Hospital, and formerly the Medical Officer of Her Majesty's Privy Council.

MR. PRESIDENT AND GENTLEMEN,—Let me, in the first place, return you my best thanks for the very kind reception which you give me. If I came before you to-night as a great discoverer, conscious of having some most important new knowledge to communicate which would change the aspect of our science, I might beyond measure congratulate myself on an opportunity (which not all great discoverers can obtain) of unfolding my valued acquisition before a large and cultivated audience. But, having no such budget to open, and feeling therefore much diffidence before this assembly which I have to address, I must remind you of your own responsibility for the flattering invitation which brings me here. In answer to that invitation, I have undertaken to put before you my line of thought on a subject which I believe you will not deem unimportant; but I fear that my treatment of the subject can hardly be such as to justify my presence here, and in proportion as this shall be the case I would beg leave to count upon your indulgence.

The reflections which I propose to bring before you relate to the present state and prospect of our knowledge of Cancer. And my choice of the subject of cancer has been determined by two motives: one, that I personally feel, and have always felt, a particular interest in the subject; and the other, a consideration which I will hereafter mention. I do not apologise to you for having written, and intending to read, what I have to say on my subject; for, though I know it to be pleasanter hearing, as well as speaking, when the speaker has at most only to avail himself of slight notes, the subject of cancer is so very large, and offers so many sidings for digression, that, unless I strictly adhered to manuscript, I could not be reasonably safe in regard of time.

Most that I have to say will relate to the causes and treatment of cancer; but it may be convenient that, in introduction, I refer, though very briefly, to two important movements of opinion which there have been within the last twenty or thirty years: first, with regard to the natural succession of facts in the evolution (if I may so term it) of a case of cancer; and, secondly, with regard to the intimate anatomy of cancerous growths. And, before I start, let me say that throughout my argument I shall always use the word "cancer" in its old-fashioned surgical sense, intending it to cover all the various tumours and ulcers which we familiarly class as *malignant*; and the word "tumour", which often may include "cancer", I use restrictedly, in its pathological sense, as meaning only *tumour by process of growth*.

I. The men who within our times have theorised on the Evolution of Cancer, have equally had before them for explanation certain broad facts in the natural history of the disease. They have seen that the tendency of persons to suffer cancer runs with marked excess in particular families, or, in other words, is in a great degree hereditary. They have seen that the natural course of a cancer, left to itself, is to pass into indefinitely extending processes of local destruction, which involve such flux of organic material as must sooner or later exhaust the general strength, and end the life, of the patient. They have seen that often before this course, as regards one cancer, can complete itself, other cancers are making progress in other parts of the patient's body, to the more rapid detriment of his life; or that, at any rate, after his death, other cancers, more or less advanced, will generally be found in his body. And, not least, they have seen that surgical removal of cancer, whether by knife or caustic, is in general of no effect to cure the patient; often because of the just mentioned presence of the disease in various other parts of the body; often, also, because the disease recurs in or near the place of removal.

The older cancer-theory of our times—the theory which was in full bloom some twenty years ago, and is even now not quite extinct, inter-

preted those facts to about the following effect. It conceived the patient to be *ab initio* the subject of a form of general ill-health or cachexia which disposed his entire body to form cancer, just as the entire body of a person incubating small-pox is disposed to form variolous pustules. His state before the cancer showed itself was a state of general cancerous tension. When a solitary cancerous tumour (say a skirrhous breast) came under surgical notice, it was regarded but as the partial effect of a diffused cause, the outward and visible sign of a tension to which it gave partial vent; and the many cancers, when they were seen, in lymph-glands and various other organs, were but the more perfect utterance of that original dyscrasy.

In this theory there was, as we now know, a large admixture of wrong inference. For the better theory which is now generally accepted in its stead, our profession has been mainly indebted to the staff of the Middlesex Hospital; in the first place, to Mr. Septimus Sibley's most instructive paper of pathological statistics, published in 1859, from the experience of the cancer-wards and deadhouse of the hospital, to which he had then recently been house-surgeon and registrar; and afterwards to the admirable practical teachings (too soon silenced by death) of the late Mr. Charles Moore and the late Mr. Campbell De Morgan, surgeons of the hospital.

The amended theory of cancer recognises no cancerous cachexia except such general ill-health as gradually results from the progress of cancer. It appeals to the fact familiar to us all—familiar even in a degree which often in a particular point of view makes the experience painful to us, that the person who comes to consult us with a cancer, a person whom we may at once see to be doomed to death within a year or two, is often to all appearance in rude general health. The theory does not necessarily pretend to explain the origin of the local disease which in such a case is brought to our notice; but, starting from that as fact, it argues what must result from it. Given (it says) one primary tumour, all other facts of the case follow from it by logic of humoral sympathy; just as, in the story of syphilis, secondary and tertiary consequences need only the one hard chancre to account for them. The cancerous cachexia, like the syphilitic cachexia, is but an affair of *progressive infection*: essentially by the juices of the body—the lymph and blood, but sometimes also accidentally in other ways; an affair only of infection, of ever-widening infection, from the one first established focus of disease. How that first focus came to be, and how it came to have its wonderful endowment of infectiveness, are questions which must be separately argued; but meanwhile (says the theory) let us frankly recognise that, where our cancer-patients show certain general signs of disturbed health, presumably this "cachexia" is the effect, not the cause, of the cancer.

II. Of late years, too, there has been change in the point of view in which pathologists have regarded the Anatomy of Cancer. Thirty years ago, cancer was supposed to be a specific new bodily texture, having (as cartilage or muscle has) an organisation proper to itself in contrast with other textures, and proper to it in all its forms. In those early days of modern histology, not all men who had picked up a smattering of Schwann were competent to understand the real physiological significance of his doctrine: and many a microscopist of those days talked of "cancer-cells" as he talked of nerve-cells and fat-cells; professing that, by the visible presence or absence of these characteristic cells which he described, every tumour would declare itself malignant or non-malignant. This (in the sense in which it was meant) was an absurd twist to be given to pathology; and I remember that even in 1847, in the first pathological lecture which I gave at St. Thomas's Hospital, I ventured to raise my voice against it. From across the North Sea, however, there was then happily beginning to be heard a voice far stronger than mine; and Virchow, rapidly laying the foundations of his now well known system of textural pathology, soon consigned to the limbo of vanity those mare's-nest "cancer-cells" of the too easily satisfied preceding decennium. The profounder and permanent work which since that time has been done in the anatomy of cancerous and other tumours is of really immense amount—immense, even if we regard only the contributions which have been made to it in the German language; but even yet it is far from complete, and the generalisations to which at present it seems to point must of course be deemed subject to correction by further contributions as they come in.

It is impossible that on this occasion I should attempt to do justice in detail to even any of the more finished sections of that immense anatomical labour; and I will only venture to describe in a few sentences what, up to the present time, seems to me their essential outcome. It seems that cancers have not, as was pretended, any one structure common to them all; that, on the contrary, different species of cancer have structures as dissimilar as the structures of bone and muscle. One principle of similarity does, indeed, apply to them all;

not the principle of likeness *per capita*, but the principle of likeness *per stirpes*. Each primary tumour has characters impressed on it, and for the most part very emphatically impressed, by what we may call its particular local parentage. The different species represent different textural origins; each texture which starts a primary cancer having, so to speak, a cancer proper to itself. Mucous and cutaneous surfaces and involutions, connective tissues, pigment-tissues, bone and periosteum, muscle-substance, lymph gland, nerve-substance, and so forth: each has its own distinctive way or ways of growing primary cancer; and, as we study the whole range of cancerous tumours, from skirrhous to glioma, we seem to see that the growth of each makes itself only gradually divergent from the normal growth-type of the texture which it represents. And as each sort of primary cancer expresses in this way more or less clearly the organ which started it, so, of course, it is in intimate structural affinity with the non-infective tumours of the same organ; and I believe that the best histologists, when they contemplate the first textural beginnings of a cancer in any affected organ, see only such simple signs of textural overgrowth as might equally be the beginnings of a non-infective tumour.

In a certain sense, however, though a sense widely different from that of the doctrine of thirty years ago, we may still say that the various sorts of cancer have morphological characters in common; but the likenesses to which I here refer are likenesses rather of expression than of feature. Thus, for instance, it seems general to cancers that the overgrowing textural elements of which they primarily consist do not develop into ripe texture, but remain more or less immature; and that in some cases they exhibit a marked reversion to very early embryonic type. It seems also general to cancerous, as compared with non-cancerous tumours of respectively the same textural parentage, that, as they grow, their first textural type soon becomes obscured: on the one hand, by the crowding of forms which, in proportion as the process is vehement, will more and more be immature or embryonic; and on the other hand by evidences, which are sometimes extreme, of the tendency of the new growth to degeneration. On the whole, then, the knowledge which anatomy hitherto contributes to the explanation of cancer is but indirect, and rather negative than positive in its bearings. The anatomical forms explain nothing in regard of the property of infectiousness which is associated with them, and which, as I will hereafter show, constitutes the real puzzle of the disease. The anatomical forms are matters of mere local accident; but the infectiousness of the cancer represents its very cause.

III. As regards the extremely difficult subject of the Causes of Cancer, it may, I think, be said that of late years we have come to estimate more fully the nature of some of the problems which have to be solved; and that, in consequence, some definite lines of study have begun to suggest themselves as tending, directly or indirectly, to throw light on the origin of the disease. Little as this progress may seem, it is, I think, not to be despised; and those who are studying the ætiology of cancer may derive the greatest encouragement, as also, I think, some most instructive suggestions, from a consideration of the wonderful advances which during the last dozen years have been made in the ætiology of tubercle.

I. A first and very strongly marked ætiological character of cancer is its preference for particular lines of hereditary succession. Superficially, it may appear that cancer in this respect only follows the lead of the non-cancerous tumours, for they also tend to run in family lines; but, on fuller inquiry, it seems little less than certain (at least so far as some of the best known forms of cancer are concerned) that cancer and the non-cancerous tumours are hereditary in two different senses. In the non-cancerous tumours, the hereditary influence seems to be the true and entire cause of the phenomenon; whereas, in some of our best known types of cancer, it seems only or chiefly to supply that part of the causation-compound which we familiarly call by the name of predisposing conditions: a distinction which, our studies of tubercle tend to show, may be one of most critical importance.

I have said that the hereditariness of the non-cancerous tumours, as compared with that of cancer, seems to be a simple matter. The non-cancerous tumours, in their most characteristic forms, belong, I believe, to the same pathological category as supernumerary toes and fingers; that is to say, they represent the same sort of idiopathic fault in the embryonic antecedents of the animal. They are local quantitative "monstrosities". True, they may not be ostensibly congenital, as the toe or finger is; but, though a part have not at birth any ostensible pleonasm of texture, not the less it may have in reserve the endowment which will afterwards evolve such pleonasm, a waiting-power like that with which the sexual organs remain undeveloped for the first sixth or seventh part of life; and the growth of the tumour, perhaps not becoming manifest till years after birth, illustrates, I believe, when at last

it comes, the deferred exercise of a congenital endowment. As to this sort of anomaly, it can be no wonder that, amid the infinitely complex movements of force and matter which fulfil the scheme of embryonic development, sometimes this or that molecule divides itself not quite normally, or sometimes this or that molecule drops ever so little out of line, or sometimes there occurs unduly this or that divergence, or this or that confusion, of molecules. It is easy to conceive that, in immeasurably small errors of this sort, germinal antecedents may establish themselves for even the most startling malformations which adorn our museums; and, among such supposed molecular irregularities, the simplest we can imagine would be that, in the distribution of matter and force among so many millions of molecules, sometimes there results here or there a supernumerary or superpotential molecule. And, as regards the hereditariness of such errors, nothing is more certain as fact than that, when once the monstrosity exists, it is apt to be fixed and appropriated as part of the transmissible type of the animal. It is not only that the tendency to form (as the case may be) the supernumerary digit or the hypertrophic tumour runs in very marked degree in lines of hereditary succession, but that in both cases we sometimes see the local endowment cling to its place of manifestation with an obstinacy which is as characteristic as inheritance,—we see, namely, that the amputated supernumerary digit, or the cut-out non-infective fibroma of skin, tends to reproduce itself locally, even again and again, as if in local restitution of a normal type.

The marked hereditariness of cancer is certainly not to be explained on hypotheses as relatively simple as those; and I do not think it to be yet proven that the hereditariness of cancer is (except sometimes in certain accidental respects) an attribute of the spot where the disease occurs.

2. A second ætiological character of cancer is the tendency which it apparently has, in some of its forms, to found itself (so to speak) on certain already-existing local disorders. See, for instance, as regards epithelioma of the skin, the very numerous cases in which the chronic raw of a common mechanical irritation, having existed perhaps on and off for years as a mere inflammatory phenomenon, has at last (as the phrase is) "taken on malignant action". And, in the same point of view, as regards the terrible liability of the female sexual system to cancer, and the conditions which make womb and breast such apt soils for the cancer-eventuality, see, and especially at the one critical period of life, how vast a quantity of common irritative unhealthiness is suffered by the two organs as incidental to their decline of function.

It is worth notice that, in this ætiological direction, cancer seems to diverge considerably from the non-cancerous (hypertrophic) tumours; for, in the pathology of the latter, it can hardly be said that any important part is played by circumstances of local irritation. It may, no doubt, be said that, in the vegetable kingdom, tumours on various parts of plants are found, in a very extensive range of cases, to arise where there is such irritant action as would in animals produce inflammation. There are the well-known and very numerous cases in which insects or acari give occasion to the tumours, on leaves and elsewhere, which are known by the name of "galls": cases, indeed, in which the animal avails itself of the plant's vital irritability to get housing of suitable pattern built for its young by the resentful efforts of the texture which it invades; and more recently it has been learnt that organic forms far below the status of insects and acari, and so minute as to be out of reach of any but skilled observation, may cause tumours of the same sort. Thus M. Davaine, investigating the gall of the Alpine rhododendron, in which a parasitic animal had in vain been looked for, finds, as the apparent cause of the tumour, a very minute fungus, with mycelium, pervading it; and a Russian botanist, M. Woronine, finds that forms of the lowest (vibronic) micro-fungi stand in apparently a like causative relation to tumours of the roots of certain plants—viz., of the alder and the garden-lupin. Cases like these are evidently frequent in the vegetable kingdom, and are perhaps to some extent represented among animals by those thickenings of texture which serve to encapsulate in the body for an indefinite time the cystic entozoa or the trichina; and also among animals a certain quantity of papillary or polypous outgrowth will sometimes be found associated with chronic inflammations of skin or mucous membrane: but, barring such doubtful exceptions, it would seem that tumour-formation of the merely hypertrophic kind is not apt to arise in the textures of the animal body in consequence of common irritation; and the relation of cancer to irritated parts would thus far appear to be *sui generis*.

3. Of all the ætiological characters of cancer, that which I think incomparably the most important is the property of infectiousness which its cause imparts to it, and which in fact makes the identity of the disease.

I need not say that in a great variety of diseases which are primarily local (including many which we can ourselves start by inocu-

lation for purposes of study) the primarily diseased part is able to infect other parts by means of the lymph and blood which it directly or indirectly transmits to them, and into which it has shed its contagium; and, in the case of cancer, evidence has long existed that those are the essential means by which the disease, when once started at any spot, tends to produce secondary and tertiary cancers in other parts of the body. Molecules, larger or smaller, of the primary cancer are always apt to be contained in the outflowing lymph and blood; and, in particular cases, the growth intrudes into veins with masses which are visible to the naked eye, and bits which detach themselves pass on with the blood till they become fixed as emboli in smaller vessels.

Secondary and tertiary cancers, beginning to show themselves in the organs which have been infected from the primary seat of the disease, invariably imitate in their structure the particular structure (whatever it was) of the primary cancer—the epithelioma, the glioma, the fibrosarcoma, or what not; and commonly they imitate it with an exactness which extends even to its minute individual peculiarities. When this remarkable fact is taken in connection with that other (which I just before mentioned) of the frequent passage of shaped texture-elements from the primary cancer into the lymph and blood, the simple theory at once suggests itself, that secondary and tertiary cancers are the outcome of a kind of natural budding-process from the primary; that living cancer-elements, floated from the one place to the other, and carrying with them a strong germ-power of their own, affix themselves as parasites to the textures which they reach, and grow there to an unlimited extent, in forms which (from the nature of the case) repeat exactly, as would vegetable grafts, the features of their parent stock. This explanation of the secondary and tertiary growths in cancer would seem to have some warrant from its simplicity; but though, as matter of fact, it seems certain that in some cases transported bits of cancer-tissue do really engraft themselves in new sites in the manner which the theory describes, such graftings appear to be quite exceptional, and their result, as regards the growth of the grafts, is questionable.

The process in which the secondary and tertiary growths in general arise is apparently of a zymotic kind; and certain observations relating to it which have been made by Dr. Creighton seem to me of quite singular interest with regard to the genesiology of cancer. In the course, namely of some elaborate cancer-studies which were made by him under the Lords of the Council—studies which it was my great good fortune to be able officially to promote, Dr. Creighton made much minute investigation of secondary cancer-nodules in liver and lymph-glands, and of various other secondary and tertiary cancers; and the explanation, which this research has seemed firmly to establish, of the meaning of such consecutive nodules, is, not that they represent the primary disease propagating itself by offshoots to new parts, but that they are autochthonic growths of the parts where they occur. It appears that, under the contact-influence of matter from the primary cancer, the textural elements of the next affected organ pass, by successive changes of their own, into growth of a new sort, by which, as it advances, the secondary nodules are gradually evolved into their wonderfully close textural imitation of the distinctive texture of the primary disease. Almost invariably this imitative growth seems to be not in any degree modified by the anatomical type of the organ in which it occurs: Dr. Creighton's single (but only partial) exception being the case of the ovary; which organ, when secondarily cancerised, seems able to add more or less cyst-formation on its own account to whatever cancer-type it has got by contagion.\*

The spreading of cancer by such a process as Dr. Creighton describes must certainly be regarded as one of the most curious of all hitherto observed facts of contagion. Pause and consider what it signifies. The primary cancer, anatomically regarded, is a definite original texture of the body, growing a modified process of growth, in which, notwithstanding its modification, the original type of the texture can be identified; and now this modified texture is seen to possess the marvellous endowment, that, coming into inoculative relations with other textures of the same body, it compels those second textures to abandon their own textural identity, and heterologise themselves to the textural pattern of the tumour. Think how, as we watch in different cases the workings of the contagium of cancer, we see the unity of that principle expressed in infinite variety of results—see the skirrhous of breast, or epithelioma of lip or tongue, counterfeited by the textural elements of the infected lymph-gland,—see some melanotic sarcoma of the choroid, or some follicular form of bowel-cancer, reproduced by the cells of the infected liver,—see the infected lung representing some osteo-sarcoma of the femur or some cysto-chondroma of testicle!

\* Dr. Creighton's valuable papers, which I hope will some day have separate publication, are meanwhile to be found in the *Reports of the Medical Officer of the Privy Council and Local Government Board* (New Series, Nos. iii, vi, viii).

And as we contemplate, in the light of Dr. Creighton's observations, the local progress of the primary disease (say some glioma of the retina, or some round-celled sarcoma in a limb), we become, I think, better able to understand the meaning of that singular so-called "infiltrativeness" which it possesses, as compared with the merely displacing power of (say) a large fatty tumour or a large collection of hydatids: an "infiltrativeness" with which it seems to abolish, but not by stretching, the various barrier-surfaces against which it comes; an "infiltrativeness" which, it would seem, may be nothing else than the circumferential contagious working of the cancer on the elements of each texture which it reaches.

I need hardly say that the ultimate meaning of these strange phenomena is beyond our present powers of explanation. Dr. Creighton's facts tend irresistibly to remind one of the molecular changes in sexual impregnation. As one sees the emigrant forms of the primary cancer melt away in the lymph-gland to which they have been borne, and then the texture of that lymph-gland begin a series of developmental changes which will eventuate in a new presentation of the parent disease, one's mind recalls the original working of the spermatogenic force which called the whole organism into being, and one is tempted to speculate whether, perhaps, the essential power of the "malignant disease", its power of specific fertilisation, may really be that the part has in activity in it (under unexplained conditions) some normal or abnormal survival of that ever-marvellous first ferment. But, if there are points of view in which that sort of speculation might seem to find encouragement from facts (and perhaps especially as regards the more fungic cancers of early life) other points of view, especially as regards skirrhous and the other epitheliomata, seem to me to suggest a widely different, though not necessarily incompatible, line of speculation. As our patient in extremity of advanced syphilitic poisoning, with tertiary gummatous tumours widely diffused among the organs of his body, tells us of the little chancre-inoculation ten years ago from which this general tumour-formation has resulted; or as we call to mind the equally demonstrable contagium of tuberculosis, and the profuse (though only military) tumour-formation which this contagium specifically promotes,—can we, with those cases before us, feel sure that no analogous exterior influence, nothing of the nature of a morbid poison, is concerned in the causation of cancer?

Our present ætiological position seems, in short, to be this. In the genesis of the primary cancer, we have evidence of two forces: one, the natural growth-power of the texture, the other a power which is at least relatively foreign; and the cancer, which will act zymotically on other organs, expresses the co-operation of those two powers. Whether the process, as regards its unknown factor, depends, directly or indirectly, on some contagium from the outer world, or is from first to last merely the abnormal play of forces native to the body, is the question which waits to be solved. In our present imperfect state of knowledge with regard to many of the requisite elements for judgment, it would, I think, be unwise to attribute impossibility to either of the alternatives. In relation to them both, as well as to other conceivable hypotheses of cancer, our scientific need and duty is to continue observing, as accurately as we can, every local and personal and hereditary condition which may seem to act, either attractively or repellingly, on the factor which it is our aim to understand; and of such indications there are already some which I think valuable. Thus, for instance, the fact (above noted) that cancer has marked affinity for organs which are already in certain accidental ways disordered, seems to show that the unknown exciting cause either is not native to the body, or at least is not specially an attribute of the texture in which the disease breaks out. And the fact (as it appears to be) that cancer, though eminently contagious from part to part in the affected body, can hardly, if at all, be communicated to any other body, even among animals of the same sort, by artificial inoculations, injections and transplantations, seems to say—first, that the unknown factor in cancer can only operate where certain general predisposing conditions exist,—and, secondly, that cancer is perhaps not an hereditary disease, except as regards those predisposing conditions.

IV. In coming now to the Treatment of Cancer, I come to what I cannot but describe as hitherto matter for most painful contemplation. We practically have no treatment of cancer (in the sense of curative or preventive treatment) except such as consists in endeavours, in selected cases, to extirpate it with knife or caustic. In a very large majority of cancer-cases, probably more than three-fourths of the entire number, there can hardly be any serious thought of recourse to this one expedient; sometimes because of the original locality and perhaps visceral relations of the disease; sometimes because the cancer, since its origin, has made too much progress; and sometimes because of conditions concerning the patient's general health. To

knife or caustic, the sole present resource of our art, we, therefore, can only resort in favour of the much smaller proportion (probably not as much as one-quarter) of our cases. And, in regard of this favoured minority, what is the good which surgery can promise? First, it can promise a microscopical hope—a hope which, on the whole, is so small as to be scarcely distinguishable from despair, that the disease will be radically cured by the operation. Secondly, it can hold out hopes, the exact nature and the strength of which will differ very greatly in different cases, but which, at their very best, are only hopes of palliation: sometimes the prospect that, under circumstances which otherwise threaten very speedy death, immediate, though only brief, respite will be obtained; sometimes the possibility (more or less) that such real check will be given to the disease as may sensibly affect the duration and (for longer or shorter time) the comfort of life; sometimes the object that particular local horrors of the disease will, if even only for a very short time, be abated. All this, taken at its best, is but poor measure of comfort for us to be able to give in respect of a disease so frequent and so dreadful as cancer. And even as much as this for but one-quarter of the cases!

Of late years, hopes have been expressed that perhaps the general prospect as regards these cases may improve under a more vigilant and strenuous application of the doctrine which we owe to the Middlesex Hospital. The opinion that cancer is at first a merely local disease implies, of course, that every endeavour should be made to remove it before it ceases to be merely local; and the line of practice which has of late been recommended in that view is in substance this:—"Except so far as there may be in the individual cases special reasons to the contrary, operate, at the earliest possible moment, with knife or caustic, as searchingly and exterminatingly as you can, on every tumour or sore which you think cancerous; and, if there be any reappearance of the disease, whether at its first site or in the lymph-glands or elsewhere, operate again to the like effect, and, should occasion arise, again, and again, and again."

As regards my estimate of that rule, I need hardly observe that injudicious persons, purporting to give effect to it, might do very objectionable things under the name of surgery; for you will observe what vastly important qualifications are involved in the exceptions of the rule. But I would not seem to dispraise the rule merely because it is difficult to apply, and therefore leaves wide room to abuse. I would judge it as in dry principle, and as if it could always receive the best possible application—such application as it would have had at the hands of Mr. Moore and Mr. De Morgan themselves, if their lives had not been cut short. And, looking thus at the rule, what are we to say of it? is it a rule which can be practically applied with any large measure of success?

So far as the arguments in its favour are speculative, I doubt whether they would justify much more hope of preventing the secondary cancerous infection by removal of the primary cancerous tumour or sore than we should have of preventing secondary syphilis by removing the primary inoculation-spot when already it had declared itself a hard chancre; whether in the one case, more (or much more) than in the other, we could expect to interpose effectively between a diseased organ and its lymph-glands, or between it and the blood, at a time when the primary infective disease had already become manifest to our senses. And particularly I should doubt whether the repeated recurrence to operations could be expected often to succeed; whether the operators would not be too closely imitating Mr. Lowe's famous Hyperboreans, who, in their horror of the north wind, travelled ever more and more to the north, in hope that at last they would get to the rear of it.

But I would not pretend to answer the real question with arguments of a speculative kind. Whether a greatly more ardent practice of operating for cancer than was in favour with our best surgeons of twenty to thirty years ago would prove itself an advance in surgery: whether our operative policy towards cancer ought to be in general (subject to proper exceptions) *aggressive*, or in general (subject to proper exceptions) *expectant*: these are questions to which no safe answer can come, except from the teachings of experience; and many years must elapse, and the experiences of many men be put together, before the answer can be given in an exhaustive arithmetically exact manner.

But, be that answer what it may, we meanwhile have the pain of knowing that even the eminent authorities whose names are most identified with the advocacy of early and (in cases of relapse) repeated operations express almost no hope of radically curing the disease by such treatment. Mr. Moore, when last discussing in print (1870) the grounds on which, in his opinion, operations for cancer might be advised, expressly said that the notion of eradicating the disease by operation can but rarely sway the mind of surgeon or patient; for that,

though there have been instances in which cancer of the lip, and more rarely of the breast, removed by operation, has not, even after many years, reappeared, such cases, on account of their rarity, can have but little influence in the decision. Mr. De Morgan, again, in the famous discussion on cancer of 1874, spoke of the "all but certainty of the disease's recurrence, remove it as we will". And this phrase of his drew an instructive comment from Sir James Paget: "I do not know", said Sir James, "what percentage *almost* means; but I will venture to say, speaking of ordinary typical cancer of the breast, or any other part which is its most frequent seat, that the number of cases in which it does not recur is not more than one in five hundred."

Now, accepting as of unquestionable authority those gloomy statements with respect to the relapse of primary cancers after removal, what but far gloomier statements can we expect with respect to the hopefulness of subsequent removals? And, returning from these details to the general statement with which I started, how can we not feel that the powerlessness of surgery in relation to cancer is a pain, if not even a reproach, to all of us?

It seems to me imperative, under the circumstances, that we should look about, with all the best intellect of our profession, to see if this state of the case cannot be amended. Little as I can myself hope ever to contribute to the object, I would at least desire at this opportunity to say how pressing important an object I consider it; and I will even venture to make some remarks on the studies which I think should be made in the matter.

Unless we suppose cancer to be in its nature incurable and unpreventable, we may conceive its cure or prevention becoming possible in either of the two following ways. 1. In proportion as the natural history of the disease shall be scientifically understood, definite indications as to curing or preventing it will be the natural counterpart of its pathology, and the resources, as they may then be, of practical medicine will be appealed to in an intelligible form; or (2) there is the chance—for it is no more than a chance—that, before full scientific insight is obtained, clinical experiments, more or less speculative, or even some discovery more or less accidental, may bring to light a specific antidote to the disease. Laboratory researches on the one hand, tentative therapeutics on the other, are, therefore, our two great lines of work; and to each of them I would give a few words.

1. Of Laboratory Researches three chief sorts are requisite: the histological, the chemical, the aetiological.

a. In histology, notwithstanding that so much work has been done, the initial stages of tumours, both cancerous and non-cancerous, have yet to be very much further investigated: on the one hand, the embryology (so to speak) of each primary tumour as collated with the structure and developmental antecedents of the organ which bears the tumour; and, on the other hand (as in extension of Dr. Creighton's admirable work) the morbid changes which first arise in the lymph-glands and other seats of each sort of secondary infection.

b. In the chemical investigation of tumours, our work is yet all to do, and offers, I think, as regards cancer, a most promising field for the worker. Particularly we want the exact chemical comparison of cancers in their riper stages with the normal organs which appear nearest akin to them; as, for instance, the comparison of masses of developed glioma with masses of (as near as may be) kindred normal brain-substance.

c. And not least, in laboratory work, we want continued exact researches into the essence of the infective process which multiplies cancer: such researches as those which, within the last dozen years, have so largely increased our knowledge of tubercle; researches, I mean, conducted by experiments on living animals, with regard to the intimate conditions of the specific infection. In recommending studies of that sort, I am not unaware, nor do I regard it as unimportant, that they inevitably involve a certain amount (which happily in the present case would not need to be a large amount) of suffering to the animals which are used for experiment. But, as cancer, one of the most dreadful of diseases, is one which affects both man and brute, so it may very greatly concern the permanent interests of brute as well as man, that, even at some present cost to the brute, those studies should be diligently followed. And if we—students of Nature and servants of mankind, acting under the best light of our individual consciences and of the collective conscience of our great profession, are ready, for the sake of human interests, to impose that first cost of brute suffering, let us hope that the caprices of impulsive legislation, and the personal discretion of successive Secretaries of State, may not render such studies virtually impossible in England to all but clandestine investigators. Let us hope, too, that, amid our serious work, the Bacchanals of an ill-informed enthusiasm, inflamed by calumny, may not rage to re-enact on some of us followers of Esculapius the unmerited mutilation of Orpheus:—

"Whom universal Nature did lament,  
When, by the rout which made the hideous roar,  
His gory visage down the stream was sent,  
Down the swift Hebrus to the Lesbian shore."

2. As regards Tentative Therapeutics, I am very strongly of opinion that, situated as we now are in relation to the treatment of cancer, our practice, in regard of cases which we do not submit to operation, ought to be systematically planned as a consistent search for more effectual treatment. Each of us should, I think, often take stock in his mind as to therapeutical resources hitherto not tried against cancer; and should, at all proper opportunities, and with the best provisional light which the pharmacology and pathology of the time can give, make for himself successive new endeavours to find a "specific" for the disease.

[By "specific," I mean in principle some influence (positive or negative) which shall be *electively* hostile to the cancer, shall be a power against the life of the cancer without being a power against the life of the body. The *Pharmacopœia* contains (I need not say) a large number of agents, such as chloride of zinc, which, so far as they can be applied to any given cancerous mass, will destroy it; but agents which do this only in respect of their being common caustics, *operating on diseased and healthy textures alike*, are evidently of no different intention from the knife; and to ring for ever the changes on common caustics, is not to touch the question of *specific* treatment. (Comp. John Hunter's *Lectures*, Palmer's edit., vol. i, p. 625.) And what I here argue in regard of the local treatment of cancer is equally to be applied when we consider the possibility of acting on cancer by internal remedies: for any treatment which operates through the blood has opportunity according to its nature to affect every organ of the body; and it would be no medical gain to poison the cancer to death if our poison were equally effective on the rest of the organisation.]

In advocating the search for a specific, I do not propose that men should refrain from knife or caustic in cases where they believe that they can clearly see their way to advantage from either; and I, of course, fully recognise that at present, in a certain number of cases, we really have no proper alternative but to operate; but, referring to the statement which I before made as to the very large number of cases in which no question of operation can be entertained, I would remind you that, even in the hands of those who are warmest advocates for operating, there must remain of necessity an immense field for trial of other modes of treatment. And let me illustrate this with reference to a particular line of experimentation, where probably the results (positive or negative) could be obtained with far more rapidity than in any other line.

Supposing the *materia medica* to contain a specific for the cure of cancer, how would you know that it deserved its name? By what test would you measure its action? No doubt we should see, under adequate internal administration of the drug, that the existing cancerous tumours, primary and secondary, affected by it through the blood, would shrink and vanish as syphilitic gummata shrink and vanish under the internal druggings which are appropriate to them; and nothing short of this would prove that we had a specific for cancer. But though full proof would not exist on any less showing than that, presumptive evidence (positive or negative) might often be got on far less elaborate showing: that is to say, if there existed such a specific as I suppose, very probably its characteristic action might be to some extent tested by the behaviour of any particular cancerous sore to which it were judiciously applied—just as, in the case of syphilis, we know the great local potency of mercurial preparations. Suppose that, experimenting in succession on a number of (non-caustic) drugs, as direct applications to cancerous sores at the surface of the body, we at last came on a drug which in a series of cases showed itself able so to "change the action" of cancers to which it was applied, that under its use the cancerous fungation would cease, and the cancerous sore would heal, evidently we should have hopeful reason to try whether the same drug, internally administered, would produce like effects through the blood, and would accordingly admit of successful use against visceral and other deep cancers to which it could not be directly applied. In thus mentioning a particular line in which I think that important therapeutical observations might easily be made, my intention is only illustrative, and I do not attempt to enter on detailed suggestions. I am content to have shown one direction (no doubt there are many others) in which most of us could constantly be making new therapeutical endeavours: for every man, with much surgical practice, is often having under his care cases of open surface-cancer, at the breast or elsewhere, with which, under present circumstances, he does (therapeutically) next to nothing; and, if his mind were made up as to any new agent he would wish to try, cautious separate use of it as a dressing to such sores or to parts of them—cautious, of course, not only as regards the sore, but also as regards the general action of the drug,

would soon furnish him with a series of facts, out of some of which, sooner or later, important hints for progress might come.

That particular suggestion, however, is, I repeat, only incidental to the main argument which I am desirous of pressing. My only essential point, let me emphatically say, is the one of general principle: the principle that we have to go to work on new lines, and with all our might, in respect of the treatment of cancer.

Among the moral qualities which go to make a great doctor, the very foremost, in relation to efficiency in practice, is a noble reluctance to be beaten. With a genius of untiring endeavour which may be summarised as "never say die," with a happy temperament of obstinate hopefulness, he fights for his patient to the very death, and, like a late eminent prize-fighter, if again and again knocked over, again and again "comes up smiling" to the scratch. You all know what a quality that is in the routine practice of medicine—how the strong man of our profession seems almost to hold back patients from the grave by the contagion of his own hopefulness—aye, and that again and again, by his efforts, he seems to win back the apparently for ever lost, and (like an older athlete than the one I just quoted) brings "Alkestis from the tomb". This great quality of the best minds in our profession, so constantly, so vigorously exercised in regard of cases which are recognised as curable, is naturally least appealed to in detail when cases stand in masses in the opposite category, generalised as hitherto never cured. But, gentlemen, is it therefore dormant in regard of such cases? Is it not on the contrary rather felt by us all that, just in proportion as the individual claim on us seems to slacken where there are those long traditions of despair, so much the more a claim is created that the collective case should be met by our collective exertions, and that, as regards every such problem of so-called "incurable disease", the whole mind of the profession should be resolutely, almost indignantly, at work?

I am particularly glad to have had the opportunity, which this evening has given me, of appealing, as regards cancer, to that strong common instinct, which I have described, of our professional heart, and of appealing to it in the presence of so many of whose sympathies I feel myself secure. And let me now say that the reason which, as additional to my own interest in the subject of cancer, led me to choose that disease as the matter on which I should speak here to-night, refers, in connection with this feeling, to the nature of your Midland Society.

The subject of cancer—partly from its very large extent and various branchings as a pathological study, and partly from the distribution of cases (which are material for study) among all practitioners of our profession, is a subject which almost absolutely requires to be worked, at least in several of its parts, by the co-operation of many persons; and I would submit that it might, with peculiar advantage, be taken up by such a Society as this for concerted work under a well-organised committee.

Medicine (I need not say) is entirely a science of observation; and any man who would pretend to improve it, except from the basis of facts, is an anachronism from days before Lord Bacon. But "facts", to be the basis for science, must be *real* facts, must be *complete* facts, must be *well-defined* facts, not theories of facts, not fragments of facts, not nebulae of facts; and scientific facts can never be established as such for joint use, except where individual experiences, brought face to face with each other, and acting in check of each other, are rectified to a common standard of description as complete as the knowledge of the time permits, and are expressed with uniform nomenclature and in harmonious methods.

With regard to cancer, moreover, it is of particular interest that the two classes of work, which I distinguished as laboratory work and therapeutical work, should be brought into intimate correlation: that the practising physician and surgeon, who may himself be unable to keep pace with the daily advances of histology and organic chemistry and experimental pathology, should be able to refer to laboratories where such advances are fully represented as well as appreciated; that the laboratory-worker should be able to get from the physician and surgeon, not only the physical thing which he may want to study, but the circumstantial knowledge which may be requisite to interpret it; and that, under joint auspices, representing the best strength of our science in each of the two great branches of work, contributions, which may be turned to universal account, should be sought in all directions, and be made matter of record and publication.

Science (says the late Sir John Herschel) is "the knowledge of many, orderly and methodically digested and arranged, so as to become attainable by one". With regard to cancer, as I think on the one hand of the vast quantities of experience, or, let me rather say, of raw materials for experience, which in this country of ours are daily running to almost absolute waste for want of some sort of organisation by which they might be shaped into science; and as I think, on the other hand,

what a Society like this might accomplish by such machinery as you could command, I see a contrast which I can only parallel by quoting the familiar antithesis of certain two possibilities of carbon: the smoke which merely obscures our day-time, and the lamp which serves as sunshine to our night.

And here, gentlemen, I conclude. That, from this great city—the birth-place and home of so many strong and wise men, the centre of so many industries, the vigorous representative organ of so much that is worthiest in English life, there may some day come help to mankind in the conflict in which our enemy now prevails against us, is the wish, the very hearty wish, with which I bid you my respectful farewell.

## A LECTURE ON RHYTHMICAL HYSTERIC CHOREA.

By PROFESSOR CHARCOT,  
Physician to the Salpêtrière Hospital, Paris.

GENTLEMEN,—In one of our patients, who has for a long time been suffering from hystero-epilepsy, with attacks of a mixed character (hysteria major), we have observed, during the last few days, a rare pathological condition, quite worthy of being placed under your eyes, but which in its nature is essentially as unstable and mobile as is, it is said, the sex in which it is ordinarily developed.

The phenomena date already several days back; but it may happen that to-morrow—perhaps in a moment, for nothing can be foreseen in this respect—they will have ceased. The occasion is, then, pressing; and it is important to seize it. That is why I have resolved to commence our conferences of this year without any preliminary remarks, without preamble, and to enter at once upon the clinical study, which is, moreover, the object which we pursue in these conferences. I shall designate under the name of rhythmic hysterical chorea the pathological condition to which I call your attention. The descriptive analysis which I am about to present to you will, I hope, amply furnish the means of justifying all the terms of that denomination.

The young patient whom you see there lying perfectly conscious of her acts is hardly nineteen years of age; her previous clinical history is, however, already very long and very eventful. I will mention to you its principal episodes in a moment. I commence at once the description of the symptoms with which I am desirous that you should become acquainted without delay.

That which certainly strikes you at the outset is, the remarkable movements by which the head, the trunk, and the limbs of one side of the body (the right side) are incessantly agitated. At the first view, these movements appear disorderly; it seems difficult to submit them to analysis. However, a more attentive examination enables us very soon to recognise a certain number of general characters. Thus the agitation may be decomposed, in each part affected, into alternate movements, especially of flexion and extension, always the same and absolutely uniform. You see the trunk strongly flexed on the pelvis

Fig. 1.

(fig. 1), carrying with it the head, which, in its turn, becomes bent upon the breast, and at one moment the forehead is scarcely more than fifty centimètres (twenty inches) distant from the right knee, which at

that moment is in forced extension. Then the head and the body are straightened, describing a trajectory, which represents a semicircle corresponding to that passed through just before in the opposite direction, in the movement of flexion; so that ultimately the back, and then the occiput, fall heavily upon the pillow; almost immediately the movement of flexion recommences, and is soon followed by the movement of extension; and so on. (Fig. 2.) It might be supposed that you

Fig. 2.

had here a profound and repeated salutation, rendered absurd by its very repetition and by its exaggeration.

Observe that these acts are reproduced with regular rhythm. To-day we count from thirty to forty salutations in a minute; yesterday and the day before, the agitation being greater, they varied from forty to eighty. At the same time, the upper and lower limbs of the right side are simultaneously extended and flexed alternately, following the same rhythm.

These movements of the various parts deserve, moreover, to be studied with attention, not only in their individual, but also in their reciprocal relations, in their isochronism. Let us take the stage at which the flexion of the head and trunk is as pronounced as possible. (Fig. 1.) At this moment, the entire upper limb is in extension; its long axis, directed vertically, forms a right angle with the plane of the bed on which the patient is lying; the forearm, extended upon the arm, undergoes also a movement of pronation, in virtue of which the palm of the hand is directed upwards. This attitude of the upper limb recalls well enough, you see, that which is produced in the mode of swimming which is commonly called *la coupe marinière*. At this moment, the leg is extended on the thigh and the foot flexed on the leg, reproducing in a very marked fashion the deformity of a talipes equinus; then the lower limb, rigid in all its parts, is strongly pressed against the mattress. The flexion of the two limbs (fig. 2) is commenced immediately after the straightening of the trunk is evident, and it progressively becomes more marked at the same rate as the latter. When the revolution is completed—that is to say, at the moment when the head and trunk, completely extended, fall back on the pillow—the forearm is strongly flexed on the arm, the hand upon the forearm, and the fingers, bent on themselves, at last touch the shoulder with their extremities. Simultaneously, and in the same proportion, the thigh is flexed upon the pelvis, the leg upon the thigh, in such a way that the heel is almost brought into contact with the corresponding buttock. This attitude of forced flexion of the limbs lasts only for an instant; for it immediately gives place to a movement of extension, which becomes more and more considerable in proportion as the flexion of the head and trunk, which has again commenced, becomes more marked.

Such is the series of phenomena which, for the last twelve days, have been reproduced monotonously with almost mathematical regularity, without cessation and without a truce, night and day, except during the few hours when sleep comes. At the moment of waking, a very curious fact occurs, to which I will return directly. The limbs, which, while the patient is awake, are incessantly agitated by alternate movements of flexion and extension, become for some moments, and especially the lower limb, the seat of muscular rigidity, resembling hysteric contraction; but this rigidity is transitory and of very short duration, and soon a series of movements of extension and flexion recommence. Observe that the limbs of the right side are alone agitated by these movements; those of the left side remain quite free. Thus, with the left hand, in spite of great oscillations of the trunk, the patient can safely carry to her mouth a glass full of water without spilling a drop. She can, further, with this hand, trace characters upon paper, and even write her own name very legibly.

Some further details are necessary to complete the picture of which a sketch has now been drawn.

Examine attentively what occurs in respect to the face at the moment when the head and trunk are thrown backward. You see that, at this moment, the right labial commissure is momentarily drawn outward and to the right. The deviation ceases at the very moment when

the head is bent forward. There is thus produced an intermittent and rhythmical grimace, which is very singular. If, at the moment when this grimace is made, you ask the patient to put out her tongue, and to make it project from her mouth, you will notice that the point of the organ is carried very strongly to the right. Involuntary movements of the tongue in this same direction are produced in the mouth every moment; and, as they coincide with the deviation of the labial commissure, considerable difficulty in pronunciation is the result. The words are cut and divided, and altered by a sort of babyish imperfection, which is strongly marked. *Chau-chou* is pronounced instead of *haouou*; *chan-chou* instead of *chaouou*.

We shall now, to finish this descriptive study from Nature, ask the patient to rise; the involuntary movements are quite as pronounced in the vertical position as they were in the horizontal. The young patient cannot hold herself upright without the assistance of her left arm, which she rests on the bed; with the help of another person, she can take a few steps forward; she then advances with a rhythmical balancing of the body, a cadenced movement of the limbs of the right side, which reminds one fairly of the dance called "mazurka". Such at least is the opinion expressed by some who are competent in such matters.

You have seen enough, gentlemen, to be led to recognise the affection which you have under your eyes as one which might be called a chorea, provided always that we take this word in its largest acceptation; so that, for example, it serves to designate affections of diverse nature where there exist gesticulations, involuntary movements of wide range, permanent movements, incessant, persistent, without lapse or truce—except, however, during the period of sleep. For this is not a case, as becomes evident from the first glance, of ordinary chorea (chorea minor, Sydenham's chorea), such as you may observe in another patient (A.), whom I have placed alongside of the first in order to better mark the contrast. In A., the involuntary movements belong to the classic type, and consist, consequently, in gesticulations which are not rhythmical, truly disorderly, and hardly describable, or which, at least, cannot be expressed by anything like a precise formula. In the young G., on the contrary, the chorea—which in this particular case is a hemichorea, since the movements of the limbs at least are limited to one side of the body—the chorea is of the kind which my colleague Professor Sée, in an important work which you know well, has proposed to designate under the name of systematic or rhythmic. (See *Mémoires de l'Académie de Médecine*, p. 95.) These qualifications, observe, are perfectly applied to our case. In our patient, indeed, the chorea may be called rhythmic, since the pathological movements affect a very regular rhythm. It may also be called systematic, since the movements in each period of the rhythm are reproduced according to a constant and uniform type.

We might seek to give still more precision to our terms, and to show that the pathological movements which we are studying should be referred to the variety of chorea called *malleatory*. Properly speaking, "*malleatory*" signifies that the gesticulations are comparable to those of the arm of the smith who strikes upon the anvil (*malleator*). But the action of striking upon the anvil is not the only one which may be imitated in this kind of chorea. If we were to persist in seeking terms of comparison in the exercise of certain physiological or professional acts, we might, looking at the movements of the arm and right leg, describe the chorea in G. as *naturatory*; or it might be more naturally called *saltatory*, if we considered, on the other hand, more particularly what occurs when the patient is erect and endeavours to take some steps, and, as she goes along, performs a sort of dance.

But these shades of difference have little real importance. It will suffice, in order to characterise the situation, to point out that, in a general way, the involuntary acts in question reproduce, more or less accurately, certain intentional voluntary acts.

[To be continued.]

## THYMOL AS A REMEDY IN SKIN-DISEASES.

By H. RADCLIFFE CROCKER, M.D.,

Assistant Medical Officer to the Skin Department, University College Hospital, etc.

TEN years ago, a paper was sent to the Pharmaceutical Society by a M. Bouillon, a French chemist, advocating thymol as a substitute for carbolic acid (*Pharmaceutical Journal*, January 1869). Since that time until lately, this substance has attracted but little attention in England; but in Germany, several have worked at it, among whom may be especially mentioned Volkmann, who has used it in antiseptic dressings, after Lister's method, instead of carbolic acid spray; and Bucholtz of Dorpat, who has made experiments upon its power of preventing or destroying living organisms in fluids, in comparison with

other antiseptics. In this country, however, it has been recently brought into general notice, mainly by the lectures of Dr. Burdon Sanderson at the London University "On the Infective Processes of Disease"; and as I have been employing it for the last five months in several skin-affections, it will be opportune to relate my experience of it. I was first shown this substance by Mr. Martindale of New Cavendish Street, who was selling it, dissolved in vaseline, chiefly as a lubricant for the finger in obstetric and similar examinations. Finding that its properties were similar to those of carbolic acid in some respects, I thought it would be useful as a stimulant application in skin-diseases, and so far it has certainly exceeded my expectations.

As when prescribing it I am constantly asked what is thymol, and the information regarding it is scattered through many publications, it may be well to give a short account of it. It is obtained from the essential oil of thyme, which is found in several plants—*Thymus vulgaris*, *Thymus serpyllum*, *Mentha sylvestris*, and *Ptychotis ajowan*, the last a very common plant in India, which would probably be the main source if much demand arose for it. Oil of thyme consists of two bodies; one a liquid hydrocarbon, thymene, and the other oxidised, thymol ( $C_{10}H_{14}O$ ). It is placed by chemists in the camphor group, and is homologous to phenol, forming thymolates and sulpho-thymolates with alkalis. As imported into this country, it is a white solid, crystallising in oblique rhombic prisms, though from weak solutions it may be obtained in the form of needles, with the odour of oil of thyme, and is obtained in the solid form by freezing the essential oil or by distillation; but when made by acting on the oil with caustic alkali, with which it combines, and separating it from the alkali by an acid, it occurs as a liquid which cannot be made to crystallise. In water it is only permanently soluble about one part in a thousand, but readily soluble in alcohol, ether, glacial acetic acid, vaseline, and fatty substances generally. Still better as solvents, both on account of the quantity taken up and because so dissolved it can be diluted to any required extent, are the caustic alkalis, thymolates being formed, I believe.

As I wished to use it in the form of lotion as well as ointment, Mr. Gerrard, the dispenser of University College Hospital, undertook to work out the pharmacy of it. The results, of which I have availed myself in prescribing, are as follows: Five grains of thymol dissolved in an ounce of rectified spirit will not be precipitated on the addition of an equal bulk of water; but some will be thrown out when diluted to four ounces to be redissolved when the proportion of six ounces of water to one ounce of spirit is reached. In the proportion of two grains to the ounce of spirit, it is miscible with water in any proportion. A solution of seven grains of caustic potash in a drachm and a half of water will take up fifteen grains of thymol. A solution of ten grains of caustic soda in a drachm of water takes up thirty grains of thymol. Glycerine only increases the solubility in water very slightly. Further details may be found in Mr. Gerrard's paper in the *Pharmaceutical Journal*.

As an outcome of the above, I have used the following formulae.

1. An ointment, consisting of one ounce of vaseline and from five to thirty grains of thymol: the thymol being dissolved in the vaseline.
2. A lotion, consisting of thymol, five grains; rectified spirit and glycerine, each one ounce; water, sufficient for eight ounces. The glycerine is added to correct the desiccating effect of the spirit alone.
3. A solution of five to eighty grains of thymolate of potash\* in eight ounces of water.

As yet, I have not had occasion to use stronger lotions than the above. I have only lately used the last lotion; but so far, have found it equally efficacious, while it has the advantages of economy and the readiness with which the strength may be increased. Ointments made with lard instead of vaseline act very well, but vaseline ointments have a better appearance. The disease in which I first prescribed it and have had the greatest success, is psoriasis.

In my early cases, I used the ointment of a strength of twenty-five grains to the ounce, to be rubbed into the seat of eruption after the removal of the scales, night and morning; but I soon found that it was a powerful stimulant, and that 5 per cent. was too strong for many cases. I must dissent from Husemann (quoted in the *Text-Book of Pharmacy* for 1876, p. 283), who has made some physiological experiments with this drug. He says: "It produces no irritation on the skin, but it does on the lips." In a concentrated form I have found it even caustic in its effects. In a case where the ointment had been carelessly dispensed, so that crystals were present undissolved in the vaseline, minute holes in the skin were produced in those parts

\* Since writing the above, Mr. Gerrard has found that the alkali merely dissolves the thymol, and that when the vaseline ointment is stronger than twenty grains to the ounce, the thymol should be first dissolved in alcohol, in the proportion of one minim to the grain.

where the crystals had remained some time. The discrepancy arises from the insolubility of the drug in water; when quite dry, Husemann is perhaps correct, but, in the presence of a solvent like vaseline or the alkaline saliva on the lips, its irritant effects are apparent. To return to the psoriasis, I found it better to begin with a weaker ointment, namely, ten grains to the ounce; and then, if the remedy were suitable, to continue as long as improvement was manifested, and if it became stationary, to increase the strength by five grains to the ounce until, in some cases, thirty grains to the ounce was reached. In the majority of cases, the weaker ointment was sufficient to cure the case; and another advantage is that it can be more continuously applied than the stronger forms, a method to be preferred, as a rule, to intermittent applications. Many cases treated with thymol showed rapid improvement, and some very chronic cases, which had resisted other treatment, including tarry applications, improved and were finally cured by it.

If the disease were limited or nearly so to its usual situations on the extensor surfaces of the forearms and legs, I usually ordered the ointment; but when the diseased surface was of considerable extent, a lotion was prescribed to be applied with soft rag several times a-day, lotions being generally more convenient in the daytime to people following their usual avocations. In some people it produces tingling and occasionally smarting when first applied, but this only lasts a few minutes. Like all stimulant remedies, it does not suit every case, and must not be applied, or at least very dilute, when, on removing the scales, the parts are much hotter to the touch than the surrounding skin and very red; in short, whenever the hyperæmia is considerable. This must be first subdued by soothing astringent measures externally, and appropriate internal medication, and then thymol applications will materially hasten the cure. In fact, it is most successful in that class of cases in which tar is usually prescribed, and while quite as efficacious and in some cases succeeding where tar fails, it is cleaner, colourless, and hence can be used on the face without producing the brown discolouration of oil of cade and other preparations of tar, while the odour is rather pleasant than otherwise.

In the later stages of eczema it is also extremely useful; some cases of very long standing, which had been submitted to other treatment of various kinds, rapidly yielded to thymol. It was necessary in eczema to use a weaker ointment of only three to five grains to the ounce; and I have not met with any case of eczema that required a stronger application than that, and unctuous are generally better than watery applications in this disease.

As might be anticipated, it is adapted to a smaller proportion of cases than psoriasis, and must be restricted to cases in the dry stage or where the amount of discharge is diminishing, *i.e.*, not until the activity of the inflammation has subsided; hence it happens that even in the same patient it would cure one part, and be too stimulating for another part where the inflammation was still active. If, however, due discrimination be employed, the duration of the disease may be much curtailed. Smarting when first put on is rather more frequent than in psoriasis. With similar precautions, it also rapidly completes the cure in so-called lichen agrius; but usually a preliminary soothing treatment is required for some time before thymol is prescribed.

Lewin and Bucholtz have shown that thymol is about eight times as powerful as carbolic acid as a destroyer of the lower forms of life, and hence its usefulness in vegetable parasitic diseases was suggested. Accordingly, I have treated cases of tinea versicolor, tinea tonsurans, and tinea circinata. In the last two I have not yet used it sufficiently to warrant an opinion as to its merits, but in tinea versicolor I have used an ointment of ten grains to the ounce and the thymolate of potash lotion of ten grains to eight ounces. The ointment was effectual, but slow in its action; but the lotion cured cases where a large surface was affected in a few days. I cannot, however, claim for it any great advantage over sulphurous acid and the hyposulphites. I may also mention, for what it is worth, that a case of lichen planus which has lasted five years, after a fortnight's treatment with thymolate of potash, shows more improvement than I have ever seen in so short a time; the itching is gone, and the eruption is less prominent.

I think we may conclude from the above facts that thymol is a valuable addition to the list of stimulant remedies for diseases of the skin, and probably also as a parasiticide for diseases of fungous origin; but, like all stimulants, it must not be used wherever there is much hyperæmia, as it will be more likely to aggravate than benefit such active cases; judiciously employed, however, it gives results which cannot fail to be gratifying to prescriber and patient, while its pleasant appearance and odour, as compared with preparations of tar, with the avoidance of the discolouration of the hair and skin produced by chrysophanic acid, are not the least of its claims to attention.

Other therapeutic uses to which it has been put are, as a caustic to the exposed pulp of carious teeth, for which it is much used by French

dentists, and as an inhalation in throat-affections; but I do not know how far it has been advantageous. I am not aware of its having been given internally, but Husemann is quoted in the *Year-Book of Pharmacy* for 1876 as having injected two grammes (thirty grains) under the skin of a rabbit weighing one kilogramme, the only effect being a slight decrease in the number of respirations and temperature and a slight increase of pulse, but probably the greater part was not absorbed. The urine was turbid, had a smell of peppermint, and contained blood-corpuses and albumen. *Post mortem* there was marked accumulation of fat in the liver, and the kidneys were inflamed. The symptoms of poisoning by it were great irregularity of breathing and paralysis setting in gradually. The heart continued to beat after all other action had ceased. So far, that would not appear to promise much from its internal administration. Its great pungency also would be an obstacle to its being given by the mouth.

## FRACTURE OF FEMUR SUCCESSFULLY TREATED BY ELASTIC PERINEAL BAND.

By DANIEL ROBERT ALCOCK, M.R.C.S. Eng., L.K.Q.C.P.I., etc., Waterford, late Staff-Surgeon, R.N.

ON June 26th, 1876, I was sent for hurriedly to see Miss J., aged 13, who, I was informed, had sustained a severe injury in the right leg in the following manner. She was running across the park, when her foot slipped into a hole that was concealed by the long grass, and she was thrown forcibly upon her right side. When lifted up, she was unable to stand, as there was complete loss of power over the right lower limb. Upon examination, the limb was found to be an inch and a half shorter than the other, and a fracture of the shaft of the femur at the upper portion could be easily detected, both by crepitus and from the extreme mobility and deformity of the lower portion of the injured limb. The foot was slightly inverted. As the patient suffered considerable pain upon any movement, she was placed under chloroform, the fractured portions brought into position, and a well-padded Liston's splint applied. The perineal pad now applied was prepared with some care, an India-rubber air-cushion being inserted, to alleviate pressure upon the perineum. There was a considerable amount of muscular spasm, with occasional jerking. As the limb was in good position, and of the same length as the other, the appliances were not disturbed. A sedative draught was ordered for the night. Sleep was frequently disturbed by the spasmodic jerking of the limb. The perineal pad had stretched, and the limb was found an inch shorter than the other in the morning. I now found that I must overcome the muscular spasm and provide constant equable extension to keep the fractured bones in apposition. As I was not able to apply a weight and pulley, from the peculiar construction of the bedstead, I decided upon using an elastic perineal band; and, after searching for some time, found what exactly suited my purpose. This consisted in a manufactured material sold in the shops as garter-elastic; it is about an inch in width; and, by employing it in layers, the necessary amount of extension power can be obtained. Two layers of this elastic I found, by a spring-balance, to exert extension force equal to that of a weight of seven pounds, which was quite sufficient for my purpose. I prepared a perineal band in the following manner. Two layers of elastic, eighteen inches in length, were covered by a sheath of soft chamois leather. Broad linen tapes were stitched to the end of the elastic, leaving the sheath free for it to move in. I had my former appliances removed, and, keeping up extension by assistance, applied a bandage evenly and firmly from the toes to the upper portion of the thigh. This very much relieved the muscular spasm. The long padded splint was then adjusted, the ankle-joint being carefully protected by cotton. The elastic perineal band was then applied well extended; this suited admirably in keeping up constant equable extension; from its narrow width, it did not interfere with the use of the bed-pan. If, at any time, pressure were complained of, by inserting the hand, and drawing down the elastic band, a soft silk pocket-handkerchief or other material could be placed between the band and the part pressed upon. Thus, in no way was constant extension interfered with. An air-cushion well inflated was placed under the sacrum. On the tenth day, some pain was experienced in the knee- and ankle-joints; and, fearing that the extension was being carried too far, I reduced it one-half, or to three and a half pounds. This last band was kept on for three weeks without any inconvenience. In the sixth week, all appliances were removed. There was no shortening of the limb, but some stiffness remained in the ankle-joint. The patient was now allowed to sit up daily, and after a few weeks she went into the country, returning here again for Christmas. I had an opportunity of

examining the limb six months after the accident. There was no shortening whatever, and the limb was as useful as the other. I could, however, still detect some thickening at the seat of fracture.

### ANKYLOSIS OF BOTH HIP AND KNEE-JOINT: OPERATION: RECOVERY.\*

By W. H. FOLKER, F.R.C.S.,

Senior Surgeon to the North Staffordshire Infirmary.

THE case which I bring before you to-day I believe to be unique, and from that fact interesting, although there was no new or unusual operation connected with it.

In October 1875, a man named Richard T., aged 23, was admitted into the North Staffordshire Infirmary. He had been attacked seven years previously with rheumatism in both knees and ankles, by which he was then confined to his bed for several weeks. Six months later, his knees were again attacked with pain, and gradually bent; the right becoming affected about a month before the left. From lying continually on his back, with the knees drawn up, the hip-joints became permanently flexed; and, in consequence of this fixed position of his hips and knees, he was bedridden until his admission to hospital. When admitted, he was emaciated and anæmic. Both lower limbs were much wasted. Both knees were firmly ankylosed at a right angle, and both hips flexed at a considerable angle, the left being quite immovable, and only the very slightest movement remaining in the right. There was no pain or swelling in any of the joints.

In May 1876, after various things had been tried and failed, his right hip was forcibly extended under chloroform, and the knee-joint on the same side excised. The bones united firmly without a bad symptom, leaving him with the slightest flexion of both hip and knee. In October, he could just manage to walk on crutches, but with great difficulty, as the left foot was much raised from the ground, and the right was unable to bear the whole weight of the body without great pain. He was very anxious to have the other limb operated on; and accordingly, on November 11th, his left hip was forcibly extended under chloroform. Considerable force was required to break down adhesions; the joint giving way with several loud cracks. I then proceeded to excise the knee by raising a flap of skin from the front of the joint; but, when this was reflected, the whole of the bones were found so firmly joined together that it was impossible to disarticulate the joint, and indeed it could scarcely be made out where it was. I, therefore, removed with the saw a wedge-shaped piece, which, though I thought at the time it would include the joint, proved to be the condyles; the upper incision cutting through the bone above them, the lower opening the joint, but leaving behind a small portion of the posterior part of each condyle. The limb was placed on a Macintyre's splint, the wound brought together with sutures, and a drainage-tube inserted.

For a few days after the operation, there was a good deal of ecchymosis round the hip, and such intense pain that it was found impossible to keep it straight. His body was, therefore, slightly raised by pillows. There was very little pyrexia, the temperature not rising above 100.2 deg. The wound healed in three weeks, when there was some union between the bones. By January 1st, this had become quite firm, and a fortnight later leather splints were applied and he was allowed to get up. The knee was straight, but there was a very slight flexure of the hip.

At first, there was some considerable difficulty in using crutches, owing to the position and stiffness of the hips and the extreme timidity of the patient; one foot also had the toes much pointed, and the ankle nearly ankylosed in that position. By exercise and patience, this was at length overcome, and in May he was discharged from the Infirmary, able to walk fairly well on crutches.

By these operations, this poor fellow was enabled to walk about by himself with only the aid of crutches, after having been confined to bed for seven years, during which time, from the position in which his limbs were ankylosed, he had been unable to get out of bed, or even turn over without assistance.

I had thought of performing subcutaneous division of the necks of the femora, to enable him to bend his body and sit down; but he became very unruly, and it was thought advisable that he should leave the Infirmary. I shall hope to see him again after awhile, and ascertain if he is still further improved and contented with his present condition; or whether, emboldened by former success, he may decide on having a little more surgery.

\* Read before the North Staffordshire Branch.

## CLINICAL MEMORANDA.

### CROUP AND DIPHTHERIA.

WITH reference to Mr. Pugin Thornton's note on this subject, I would draw his attention to Dr. Carl Weigert's paper in the August number of Virchow's *Archiv* (1877, p. 461), entitled "Ueber Croup and Diphtheritis". Dr. Weigert has repeated the experiments of Brétonneau, Stricker, Reitz, and others, by injecting irritating substances into the larynx, and he has studied the histological appearances of the resulting changes. These, he finds, present the peculiar transformation of the epithelium and the other characters of croup in the human subject. This is an important argument in favour of the non-specific nature of the inflammatory process; it has been hitherto held that the false membranes produced in similar experiments have only a superficial resemblance to the true pathological formation.

ROBERT SAUNDY, M.D., Birmingham.

## OBSTETRIC MEMORANDA.

### DIVIDED PLURAL LABOUR.

I THINK the rarity of cases like the following will justify its publication. On January 18th, a midwife delivered Mrs. Bishop, of Richard Street, Birmingham, of a full-grown healthy male child. On the third day after her confinement, she came downstairs and resumed her ordinary employment, feeling quite well. On the morning of February 4th (the seventeenth day after her former accouchement), she sent for me, stating that she felt the sensation of something moving in her abdomen. Very shortly after my arrival, I delivered her of twins, a boy and girl, each one being full-grown and quite healthy. The placentæ were softened and more of the consistence of jelly than anything else, and had to be scooped away by the hand. However, the mother and three children are doing exceedingly well, and the uterus is rapidly resuming its natural size. The most remarkable feature of the case is that, all through the case, there has been an entire absence of "pains", and she observed to me that, had she been asleep, she does not think that my manipulations in delivering her would have awoken her. She is the mother of ten children besides the above, and is a corpulent, strong, and healthy woman.

J. R. H. LUMBY, M.R.C.S., L.R.C.P.E., Birmingham.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

#### CHARING CROSS HOSPITAL.

MR. BARWELL'S WARDS.

*Two Cases of Successful Operation for Aneurism of the Innominate.*—C. II., a domestic nurse, aged 27, well nourished but slightly built, was admitted to Mr. Barwell's wards, presenting the signs of aneurism of the innominate artery. She had always enjoyed good health till her present illness, with the exception of an attack of rheumatic fever at the age of fourteen, which did not appear to have left behind any heart-mischief. She had never been engaged in heavy work. About Christmas 1876, she began to suffer from palpitation and breathlessness, with pain in the region of the sternum, increased by taking food, and these symptoms never completely left her. In March 1877, she came under the care of a surgeon in the country, who noticed abnormal pulsation above the right clavicle and in the carotid region. Rest gave her some relief; but, on resuming her work, the symptoms soon returned. When she came under Mr. Barwell's care at the beginning of the present year, there were distinct signs of aneurism of the innominate, and strong pulsation was seen in the right common carotid; but there was scarcely any visible tumour; the right radial pulse was stronger than the left. There was no cardiac murmur, and the aneurism appeared to be purely confined to the innominate. A week after admission, she was placed under the influence of ether, and the carotid and subclavian arteries were simultaneously ligatured, antiseptic precautions being used. She rallied well from the operation; the next day, there was intense headache, not localised, and the fingers of the right hand were

somewhat numb. Four days after operation, the right radial pulse was faintly perceptible, though no pulse could be felt in the brachial or temporal arteries of the right side. Within a fortnight, the wounds were healed. When seen three weeks after operation, the aneurism appeared to have consolidated, and the patient was in every way in a satisfactory condition; the right radial pulse was distinct, though feeble; no pulse, however, could be felt in the axillary; it appeared, therefore, that collateral circulation was being re-established.

The second case was that of a woman, L. G., 37 years of age, a widow, who had worked hard in a small shop, where she often had to lift heavy weights. Two years ago, while engaged in hard work, she felt great pain in her back, and from that time has been troubled with breathlessness on slight exertion, so that she was obliged to seek a light situation as housekeeper. In October 1876, she complained of shooting pain in her right chest, not localised; she also began to suffer from cough, breathing became laboured, and she felt ill; she also suffered much from vertigo, and was unable to obtain any relief of these symptoms. Her nights had been restless, and she had been unable to lie down, on account of irritative cough. Latterly, a swelling formed and rapidly increased in the region of the innominate. When she came under Mr. Barwell's care, there was a distinct pulsating tumour, extending from the second right costal cartilage to the sterno-clavicular articulation; it measured 2.5 inches vertically and 1.5 inches transversely. The radial pulses were equal. After she had been kept quiet in bed for a fortnight, a ligature was applied to the right carotid and subclavian in the third part of its course. She slept well after the operation; but, next day, suffered intense headache, and pulsation in the tumour continued. A week later, the wounds had nearly healed, and the patient had recovered well from the operation, but complained of numbness in the right arm; pulsation in the tumour was lessened. When seen two months after operation, there was some pulsation over the right chest, which appeared due to dilatation of the aorta; the innominate aneurism appeared to be solid.

*Epithelioma of the Eye.*—A woman aged 47 came under treatment as the subject of epithelioma of the eyelids and conjunctivæ. Her health had always been good. Fifteen years ago, she noticed a little wart on the left upper eyelid; this was cut out a twelvemonth later. Five years ago, a growth started from the old scar and extended towards the inner canthus; this was cauterised and, for another year, gave her no trouble. Then the upper lid, inner canthus, and lower lid became involved in the growth, which steadily increased and extended on to the conjunctiva. On admission, a large fleshy growth involved both the upper and lower eyelids, entirely covering the eye; the mass extended downwards as far as the malar protuberance and nearly to the left ala nasi. Mr. Barwell made a clean removal of all the diseased parts, emptying the orbit and scraping out the lacrimal duct with a tenotome. At the same time, a simple sebaceous cyst in the neck was removed as a precautionary measure, such tumours being apt to degenerate in the subjects of cancer. The patient has made a good recovery, and a scar of moderate size remains.

*Labio-glossolaryngeal Paralysis.*—A middle-aged man was sent into the hospital, with the expectation that tracheotomy would be performed for the relief of his urgent difficulty of breathing. The dyspnoea was found to depend upon laryngeal paralysis, and it was observed that the right half of the tongue was much atrophied; there was also some weakness of the muscles about the mouth, on the right side, and difficulty in swallowing. Distinct indications of syphilis were obtained, and mercurial treatment was at once resorted to. The case appeared to be one of bulbar paralysis, and recovery soon commenced under this treatment, without any necessity for surgical procedure.

*Removal of Loose Bodies from the Knee-joint.*—A young actress, while performing at a theatrical rehearsal, felt her left leg suddenly give way under her with great pain. When examined, a distinct protrusion was found at the inner side of the knee. Mr. Barwell made an opening into the joint over the protrusion under the carbolic spray, and removed a large lipomatous growth, which extended into the joint; also several smaller ones in its vicinity, which were not actually in the joint. The wound was dressed antiseptically and kept immobile. The healing process proceeded rapidly without any drawback, and was complete within a fortnight.

*Excision of the Hip-joint.*—A little boy of very strumous tendency was brought to the hospital some months ago, on account of advanced disease of his left hip-joint. His general health was then very bad, and he was also suffering from strumous disease of the clavicle and one finger. On these grounds, the case was considered unfavourable for excision. He lately returned to the hospital with a large abscess in the neighbourhood of the diseased hip; it was then determined to give him the chance of benefit by operation. Excision was performed. He made a good recovery; all sinuses have healed up; his general

health has improved, and the disease of the clavicle and the finger is also relieved. The operation has quieted his strumous tendencies, instead of aggravating them, as is sometimes the case.

*Excision of the Lower Jaw for Sarcomatous Growth.*—An old man had undergone a minor operation for removal of epithelioma of the lower lip two years previously, and lately came under observation as the subject of recent sarcoma of the lower jaw. The skin over the tumour was much involved, and it was evident that nothing short of a radical operation would avail anything. Accordingly, Mr. Barwell removed the left side of the lower jaw by a rapid operation; the bone was divided at the symphysis and disarticulated behind the tumour, with the skin over it, the sublingual and parotid glands being removed at the same time; the sheath of the carotid vessels was almost laid bare, but there was no great amount of hæmorrhage. The tongue and palate were not involved. When seen three days after operation, the patient was going on well.

*Subcutaneous Osteotomy.*—A healthy man aged 60 was much troubled by the deformity of one leg, which had resulted from a previous compound fracture. Both bones were divided with the chisel above the ankle-joint. Some little difficulty occurred at the time of the operation in getting the limb straight after the section, as both bones were united together, and there was much old callus. The bones were, however, brought into good position and immobilised. He has made a good recovery, with a straight limb, notwithstanding his age.

#### DR. GREEN'S WARDS.

*Intrathoracic Abscess.*—A strumous-looking boy presented an abscess as large as an orange at the upper part of the right chest; it pointed above the right clavicle, and the skin over it was inflamed. The pus was evacuated with antiseptic precautions, and the boy has made a good recovery. Dr. Green considered the question as to whether the abscess was probably local and extrapleural, or a localised empyema. In favour of the former view, were the facts that the physical examination of the chest indicated a strict localisation of the cavity of the abscess to the upper anterior and lateral regions of the right chest, the other regions of the thorax presenting normal signs. Also a localised empyema is usually preceded by the history and signs of general pleurisy; in this case, the lung and pleural cavity appeared healthy, and there was no history of disturbance previous to the appearance of the abscess. The boy had shown a strumous tendency, having suffered from a popliteal abscess a year before. There were no signs of disease of bone or of the clavicular joints.

*Quinine in Enteric Fever.*—A woman aged 34, suffering from enteric fever, was admitted to the hospital on the eighteenth day of the disease. There was a distinct rash and the diagnosis was complete. There was no special intestinal trouble or complication; but the temperature averaged 105 deg. Fahr., without remissions, till the end of the third week. The patient became exceedingly ill by that time, extremely prostrated, unable to take nourishment, failing circulation, delirious, and falling into the condition described as "the typhoid state". On the twenty-second day of the disease, at 3 P.M., the patient was in the condition described, and appeared as if she would soon sink; temperature 103.5 deg. Fahr. Dr. Green then ordered twenty grains of quinine, with two ounces of brandy and an equal quantity of warm water, to be taken at once; within two hours, the temperature had fallen to 102.3 deg. Fahr., the pulse had improved, and the patient seemed in every way better. The dose of quinine was repeated twice, with brandy, during the day; at the same time, beef tea, eggs, and milk were given at short intervals, with intermediate doses of brandy, of which she took thirty ounces in all within twenty-four hours. At the end of that time, the temperature had fallen to 98 deg. Fahr., and the patient was in every way better: the delirium passed off, and convalescence was soon established. Though the temperature rose again to 102 deg. Fahr., there have been daily remissions, and the patient has progressed satisfactorily.

*ELECTRIC TREATMENT OF BURNS AND SCALDS.*—*A propos* of cures for burns and scalds, I extract the following from the second edition of James Ferguson's *Introduction to Electricity*, 1775. "One time my wife happened to scald her wrist by boiling water. I set her upon the glass stool directly, and took sparks from the wrist. In a short time, the redness of the skin (occasioned by the scald) began to disappear and she felt immediate relief. A linen bandage was then put round her wrist, and in a few hours after, I repeated the operation, which entirely cured her, and there was not the least blister on the skin, nor any difference in its colour from what it had before the accident. If it had not been taken immediately, and before a blister had risen, perhaps electrifying would have been of little or no service."

F. W. COCK, JUN.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 12TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

## AN ANALYSIS OF SEVENTY-FIVE CASES OF "WRITERS' CRAMP" AND IMPAIRED WRITING POWER. BY G. V. POORE, M.D.

IN seventy-four of these cases, the condition of the hand completely overshadowed any other disease, whether general or local, from which patients were at the time suffering. Most of the cases merited the name of "writers' cramp", or had been so-called; but the author purposely included a few cases which obviously did not merit that name, because the study of them threw some light on the main question. The cases fell naturally into six groups: 1. Paralytic (six cases); 2. Spasmodic (five cases); 3. Degenerative (nine cases); 4. Neuralgic or neuritic (nineteen cases); 5. Writers' cramp (thirty-two cases); 6. Anomalous (four cases). The cases were arranged in a tabulated form. It was shown that, since the ulnar nerve supplies thirteen and a half out of the eighteen intrinsic muscles of the hand, its integrity is very necessary (more necessary than that of any other nerve of the hand) for all delicate manipulation, especially writing. The spasms which affect the hand, and which are particularly prone to follow attacks of hemiplegia, owe sometimes, there is good reason to believe, their character, if not their origin, to a faulty antagonism (due to a secondary paralysis or paresis) among the muscles of the paralysed limb. Although it is commonly received that such spasms are due to disturbance of the grey cerebral matter, it is well to look also to the peripheral aspects of the question. Provided a nervous impulse issuing from the brain be distributed in a limb to equally irritable muscles which mutually antagonise each other, it is difficult to conceive that spasm of definite form should be produced; but, should the equilibrium of antagonisation in the limb be destroyed by a secondary lesion, the production of definite spasm is easily conceivable, especially when voluntary control is lessened by a lesion of the central ganglia. In some cases of localised spasm, there is no evidence of central change, and it is theoretically possible that the action of a disordered centre on a healthy periphery and the reaction of a disordered periphery to a healthy centre may be identical in their results. Loss of writing power is often the first and most prominent symptom of degenerative change occurring in the spinal cord or brain. The neuritic or neuralgic group is characterised by a painful and tender condition of the nerves of the limb, which may be induced solely by overwork, but more frequently by a strain or similar injury combined with exposure to cold and a depressed state of health. Of the nineteen cases in this group, twelve were females. Any attempt to use the arm either for coarse or fine acts produced fatigue, pain, and neuralgia. It is not always easy to distinguish these cases from true "writers' cramp", and, indeed, there cannot be said to be any hard and fast line between the two groups; but it is characteristic of the neuralgic group that—1. The symptoms involve a wider area; 2. The symptoms are sometimes induced without excessive exercise of any function; 3. Nerve-tenderness or neuralgia is a prominent symptom. In the group of true "writers' cramp", considerable care is necessary to detect peripheral evidence of mischief; but the author stated that, in every case of impaired writing power which he had seen, there had been evidence more or less marked of derangement of one or more of the muscles used for writing. This evidence consisted of—1. Obvious failure to use certain muscles efficiently either for writing or for some other less complicated act; 2. The occurrence of consentaneous movements or tremor when certain muscles were put in action; 3. Depressed or exalted electric irritability; and 4. The occurrence of sensory derangement or nerve-tenderness. The muscles which are most frequently involved are those of pen-prehension rather than those of pen-movement. Reviewing the cases as a whole, attention was directed—1. To the inferences which may be drawn from an inspection of the handwriting; 2. To the fact that joints were found to be implicated no less than twenty-one times, the joint-affection being rheumatic, neuropathic, gouty, or due to strained position; 3. To the fact that a difficulty in writing is not very infrequently hereditary, or developed very early in life; and that 4. Any evidence of involvement of the nerve-centres is decidedly rare. "Writers' cramp" has been spoken of as a disease of "faulty co-ordination", and there can be no doubt that such is the case, for it is evident that the muscles used for writing fail to work orderly to-

gether. We are not, however, justified in assuming the existence of a special co-ordinating centre for the controlling of the act of writing; and the author had been unable to find evidence that this centre (supposing it to exist) ever gives way, leaving the periphery, except for the special co-ordinated act, in a state of perfect health. The existence of such a centre appeared to the author to be improbable, for the following reasons. 1. He had never seen a case of writers' cramp without peripheral evidence of change; and in the majority of cases there had been no evidence of any change other than peripheral. 2. If there be a co-ordinating centre for writing, it must be created, as it were, by education. The co-ordination of writing, which we are many years in acquiring, must be distinguished from those co-ordinated movements (such as the symmetrical movement of the two eyes) which are wholly independent of education. The fact that no two people hold their pens exactly alike, and that it is scarcely more difficult to write with the toes than with the fingers is much against the probability of the existence of a writing centre. 3. Writers' cramp is never suddenly established, as aphasia sometimes is. 4. It is almost certain that a purely peripheral lesion may cause all the symptoms of writers' cramp. 5. The fact that the left hand (if used for writing) sometimes suffers as well as the right, is no evidence that the change is central. In previous writings, the author had spoken of "writers' cramp" as a "fatigue disease", and he was still inclined to adhere to the word "fatigue" as a convenient expression for an easily recognisable and familiar condition of the pathology of which we are uncertain. He was inclined to think that occasionally fatigue is the expression of hyperæmia or mild inflammation of a motor nerve, and that the same condition may be produced either by overwork or by accidental causes, such as cold, strain, "rheumatism", or injury. Fatigue especially attacks those muscles which are subjected to prolonged strain; and it is probable that the relative frequency of "writers' cramp", as compared with other professional ailments, is due to the fact that prolonged strain of certain muscles (those which hold and steady the pen) is inseparable from the act of writing. Finally, as to the position of "writers' cramp" in the catalogue of diseases, the author would feel inclined to class it with neuralgia; that is, with a disease, the phenomena of which are purely local, but which we recognise as being due not only to conditions affecting the sensory area involved, but also to molecular change affecting any part of the sensory fibre, whether before or after its function with the nerve-centre. The author concluded by laying down certain principles of treatment for the various forms of impaired writing power.

Dr. BUZZARD, after complimenting Dr. Poore on the complete and exhaustive character of his paper, said that he had seen many cases of so-called writers' cramp, and quite agreed with Dr. Poore that it could not be regarded as a disease *sui generis*. It presented itself in different conditions and required different modes of treatment. There was one cause of writers' cramp to which Dr. Poore had not referred—the wasting of muscles from lead. He had found in one case almost complete loss of irritability in the thenar eminence. It could not be traced to traumatic lesion or muscular atrophy, but, on examining the water which the patient used for drinking, he found it to contain lead. In several cases which he had seen, the electric irritability was increased on the affected side; these were connected with gout, and were relieved by the proper remedies for that condition. Dr. Poore regarded true writers' cramp as a fatigue disease of the periphery, and not of the centre. He (Dr. Buzzard) thought that the tendency of the disease to spread to the muscles of the arm and shoulder, and sometimes to affect also the left hand, indicated a central rather than a peripheral origin. There was no doubt that special centres for certain co-ordinated actions, such as writing, could be formed in the course of generations by education. He had always thought writers' cramp a central lesion, produced in the following way. An undue use of the special act caused congestion of the centre, and this led to interference with the nutrition of the muscle over which the nervous centre presided. Centres of recent formation—such as that for writing—would be more liable to disturbance than that for the co-ordination of the movements of the eyes, which had existed as long as man himself.—Dr. BROADBENT agreed with Dr. Poore that writers' cramp was a peripheral and not a central disease. The author of the paper had made a great step in advance in directing attention to peripheral nervous diseases, which were too much neglected. He would reject the idea of a special centre of co-ordination for writing. There was too much readiness to postulate centres of co-ordination. Dr. JOHN HARLEY asked what the author meant by the term peripheral, seeing that he regarded the disease as affecting both the muscle and the nerve.—Dr. POORE, in replying, said that if there were a special centre it must have some locality, and there would be some indication of this, such as pain, etc., but he had never been able to find any.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 22<sup>ND</sup>, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Two Cases of Psoriasis (Living Specimens)—the one treated by prolonged daily Immersions, the other treated by an Ointment of Chrysophanic Acid.*—MR. BALMANNO SQUIRE exhibited these cases. One was that of a gentleman aged 32, who had been extensively affected with psoriasis for nine years. He was kept under treatment by prolonged daily immersion in tepid water for exactly six weeks, during which time he submitted on the average to five hours' daily immersion. The temperature most readily borne by the patient during a prolonged immersion was about 90 deg. Fahr. By the end of six weeks, without other treatment of any kind, the patient had lost by far the greater part of his eruption, which presented now only a fifth, or at the most a thirtieth, of its original area, and had also got rid of the nocturnal itching which accompanied it. He was now treated with phosphorus "perles" and chrysophanic acid ointment; and in ten days, time presented only such insignificant traces of the disease that he decided to return home to his duties. Prolonged daily immersion in tepid water had for very many years been employed in the treatment of skin-disease at Leukerbad in Switzerland and at Baden near Vienna; but this case would seem to show that the less irksome ordeal of spending some hours daily in the bath, could suffice to produce fairly good results. The other case of psoriasis was that of a gentleman aged 34, who had been affected with the disease for twelve years. The eruption was chiefly massed over the belly and the loins. He was ordered the use of chrysophanic acid ointment, of a strength of twelve grains of the acid to the ounce of lard; and he was furthermore directed to take two phosphorus "perles" (containing each one-thirtieth of a grain of phosphorus dissolved in oil) three times a-day. On the fourteenth day of treatment, the patient conceived an impression that the phosphorus was impairing his mental energy, and accordingly he was permitted to discontinue taking the perles. By this time also, the erythema, excited by the chrysophanic acid, had entirely subsided. The patient was therefore ordered to resume the use of chrysophanic acid ointment, now made stronger than before; namely, a drachm of the acid to the ounce of lard. In three days' time, that is to say, on the seventeenth day of treatment, all trace of the eruption on his body had completely disappeared, the chrysophanic acid ointment having again excited some erythema. On the twenty-fourth day of treatment, the disease still existed on the arms and legs, local treatment with the chrysophanic acid ointment having been still persevered with to the limbs, although, since the seventeenth day of treatment, no further applications had been made to the body, inasmuch as every sign of the disease had gone from the trunk. The patient still exhibited traces of the disease on the limbs.

Dr. TILBURY FOX said that the case cured by immersion confirmed what was already known on that subject, but in private practice the method was hardly applicable. Few could afford the time necessary. The case recorded was one of indolent and chronic psoriasis, and the treatment succeeded, but generally failed when fresh crops were coming out. The other was similar in character, and more than one remedy would suit such cases. For instance, mercurial and carbohc acid ointments would do, so would alkaline baths, and so on. The earlier and more acute stages were more difficult to treat, and here a specific could hardly be sought for. For instance, one form was apt to occur in married women from oversuckling; others, again, in gouty subjects, where totally different lines of treatment were demanded. Again, there was the rupioid form, tending to occur in children, where cod-liver oil suited best; and still, again, the malady was apt to occur among over-wrought city men, where the digestion was the chief thing to be looked to. It was only in the essentially chronic form that chrysophanic acid could be said to do good, but it stained both the skin and the clothes, and patients did not like it.—MR. HUTCHINSON said patients should be warned of the effects of the acid, for often severe erythema followed. What was the real meaning of the word "cure" in psoriasis? It ought to mean relief permanently, or else for a period of years. It was easy to get rid of the scaly symptoms for a period, but what of a longer time? Hebra used bathing, but not the bath referred to; rather a big one, into which half-a-dozen patients may enter, and scrub each other with coal-tar soap for six hours or so at a time. Cures, as he called them, followed. He thought arsenic and tar, both externally and internally, did much good.—Dr. R. LIVEING could confirm what had been said as to the objections to chrysophanic acid—patients would hardly put up with it. He himself had long used it for ringworm, but the patients complained of the dirty mahogany colour it gave to their hair. He had long used baths with soft soap and flannel, and on this

method half-an-hour a-day sometimes sufficed for a cure. Acute cases constituted the real difficulty.—Dr. R. CROCKER said that, while there was no doubt the bath treatment, as adopted by Mr. B. Squire, was very effectual, a similar result might often be obtained by simpler and less inconvenient means, and related a case of severe universal psoriasis, present more or less for twenty years, which was cured, in the sense alluded to by Mr. Hutchinson, in about three months by alkaline baths for half-an-hour twice-a-week, and diuretics internally. As for chrysophanic acid, he had used it somewhat extensively two years ago in cases of ringworm, but had almost abandoned it, except in parts concealed by the clothes, on account of its limited success and unpleasant effects. He had shown a case at the Harveian Society where it had dyed the hair a purplish brown, as mentioned by Dr. Liveing; and, at the time when he was using it extensively, he often recognised his patients in the street by the colour of their hair. Moreover, its effects were not confined to the part to which it was applied. In some cases in which only the scalp was treated, a coppery red erythema spread over the face and neck, accompanied by oedema of the eyelids and sometimes slight conjunctivitis, the eruption terminating in a few days in a dirty-looking desquamation. Being such a powerful irritant, it was only suitable for carefully selected chronic cases, whilst many would be aggravated by it.—MR. MORRANT BAKER had used the acid, and thought it the most rapidly acting remedy for psoriasis, but it acted on other parts of the skin than those to which it was applied. This might in the end turn out a valuable property. One of the cases he could hardly call psoriasis, it seemed more like a parasitic disorder.—Dr. H. WEBER referred to his experience of patients sent to bathe at Leuk (Louèche), where it was the custom to pass from four to six hours in the water in the morning, and again from two to three in the afternoon. In some cases, this lasted from four to eight months; but all his cases were of long duration. Only one of his cases was cured, and that was the most recent. In all the others, the malady returned within two years.—Dr. WHIPHAM considered that the acid should be used with caution. In one girl, who had suffered from psoriasis for five years, the acid was applied to the eruption only, yet the face swelled up as in erysipelas. In a more recent case, in the person of a flour-miller, where the disease chiefly prevailed where there was rubbing, on the arms and legs, the ointment caused pustules and boils on the skin round about.—MR. B. SQUIRE, in reply, said he considered the balance was decidedly in favour of chrysophanic acid. He could hardly think it more easy to cure a chronic than an acute case, though the latter yielded better to internal remedies. He did not like the use of arsenic, but preferred external treatment. The acid, no doubt, required careful handling; but other things did the same. The hair only became discoloured after the use of soap and water, and the dye could readily be removed by means of benzole.

*A Case of Eruption from Bromide and Iodide of Potassium.*—Dr. RADCLIFFE CROCKER read the report of this case. The patient, a labourer, married, aged 49, was sent from the hospital in Queen Square to University College Hospital on February 5th, with a peculiar eruption for diagnosis. Recognising it at once as a bromide of potassium rash, Dr. Crocker obtained the following history. He was treated at Queen Square Hospital four years ago for right hemiplegia with aphasia. He never had rheumatic fever nor syphilis. On January 8th, 1878, he was readmitted as out-patient at the Queen Square Hospital under Dr. Bastian, having had a fit of an epileptiform character the day before, which left slight weakness of the right side and dropping of the right angle of the mouth. For this, ten grains of bromide and five of iodide of potassium were prescribed three times a-day. This was continued up to February 4th, i.e., nearly a month, when it was changed for an effervescent mixture. The eruption began in the form of "pimples" on the cheeks on January 23rd, and developed into patches, as now seen, by the 27th. When Dr. Crocker first saw the case, on February 5th, it presented the following characters. On each cheek was an irregular considerably raised patch about the size of a crownpiece, of a dull, livid, red colour, giving a boggy almost fluctuating feel to the finger. The central part was occupied by a brownish-yellow scab, but at the periphery numerous yellow points were observable, which, on close inspection, could be seen to be the apices of partially coalesced papules. On pressure, fluid exuded, which being examined under the microscope, was found to consist of pus-cells, epithelium, and sebaceous matter dissolving in ether, with some blood-corpuses. Smaller patches of evidently aggregated papules were present on the end and ale of the nose, and a few discrete round pink papules a quarter of an inch in diameter, some of them with yellow apices and softened bases, were seen on the cheek, nose, and upper lip. As seen at the Society on February 8th, the yellow points were no longer visible, and the composition of the patch by the aggregation of papules could not be made out. The right patch, which came out four days

before the other, was now covered with a thick brownish yellow and blood-stained scab, bleeding, which was described as spurting out, having occurred twice. On the left cheek, only the lower half had the crust upon it; the rest was livid, red, and fluctuating, and the solitary pimples had also dried into crusts, while their bases were softened. There was no eruption in any other part of the body. Dr. Bell of the Birkbeck Laboratory at University College was kind enough to examine the urine, and found iodine, but could not detect any bromine; its specific gravity was 1030; it was very acid, contained much lithates, but no albumen or sugar. This case formed a pendant to that of an infant with a similar eruption which Dr. Crocker showed to the Pathological Society about a month ago. The following points were of special interest: 1. The moderate dose of bromide of potassium; only ten grains three times a-day for a month; 2. The fact of iodide being given with it; 3. Absence of eruption on the limbs; 4. Its being really only an aggregated form of acne; 5. The absence of bromine in the urine. Dr. Crocker alluded to many other cases described by English and continental observers; in many of which, when the rash appeared, it was believed there was some iodide present as an impurity in the bromide. But Dr. Crocker thought there was no doubt, from recorded cases, that bromide of potassium alone would produce it.

Mr. NUNN had never seen such a case, though he had given both bromide and iodide very largely. They could only be sure it was a bromide rash if it ceased with the cessation of the administering of the drug.—Dr. TILBURY FOX said there could be no doubt that the rash was a bromide rash. He had seen many such. Both the bromide and iodide rashes were of the same kind; but the rash was most likely to follow where both were given in combination.—Dr. GLOVER referred to the case of a child, mentioned by Dr. Tilbury Fox. It was six or eight weeks old, and was not taking bromide; but the mother was, and had been doing so for a long time. There was no doubt as to the nature of the case.—Mr. HUTCHINSON also confirmed the diagnosis. He had seen some very bad cases, in some of which the eruption ensued again and again. It was not a question of dose, but of idiosyncrasy.—Mr. BAKER thought there was no doubt as to the nature of the case. There was no bromine or iodine in the urine that might help to account for it.—Dr. MAHOMED referred to a case he had seen at St. Mary's Hospital. The patient died of chronic Bright's disease. He suggested that this man too had contracted kidneys.—Dr. CROCKER was glad that there was an unanimity as to the nature of the disease. Idiosyncrasy was, no doubt, the clue to these cases, though probably the urine might have something to do with it; but it was not likely. In France, the cases referred to were far more common and more severe, the dose given being apparently larger. It was not easy to separate bromine from urea.

*Two Cases of Cancer of the Breast of Opposite Extremes of Duration.*—Mr. NUNN read a paper on this subject. He commenced by referring to two cases of a parallel character, particulars of which were communicated to the Society on November 22nd, 1872, and to the questions, amongst others, that appeared to press for consideration, namely, What was it that rendered cancer-cells stationary, and retaining them *in situ* permitted their undergoing degeneration without encroaching upon and infiltrating contiguous parts? and what, on the other hand, caused their wide distribution and proliferation in distant regions? What share had inflammatory action in stimulating proliferation and promoting diffusion? The two cases now brought before the Society presented opposite features; one terminated fatally within eight months, the other continuing to live on after the lapse of six years, four of which had been spent in the Middlesex Hospital under the author's observation. Case I, aged 45, had a lump form in the breast after a blow that had almost been forgotten; rapid solidification of the entire mamma, and brawny oedema of the side of the thorax and upper extremity, followed, accompanied by excessive painfulness. The *post mortem* examination showed that the whole mamma was the seat of cancerous deposit, that the axillary glands of both sides were affected, the right lung adherent, the left patched with cancer-deposit, the pleural cavity containing sixteen ounces of turbid fluid.—Case II was admitted in November 1873 into the Middlesex Hospital, where she still remained. The tumour was about the size of a duck's egg, and no axillary glandular complication existed on admission. The tumour, after a year's residence in the hospital, inflamed; and an axillary gland was found to have enlarged in April 1877; and, in January 1878, acute necrosis destroyed first the centre, and secondly a part of the circumference, of the tumour, a delicate cicatrization having covered the cavity left by the slough after the first attack. The author expressed his belief that, in cases of the early appearance of brawny swelling of the upper extremity, commencing at the side of the thorax and extending downwards, the lympho-canalicular system was the structure primarily involved. The observations of Köster of Würzburg were alluded to (*Die Entwicklung der Carcinome*,

1862), and the criticism of Waldeyer (*Sammlung Klinischer Vorträge*, 1872) was mentioned. The author urged the importance of shielding a cancerous tumour, previously to operation, from all mechanical and other violence, and the adoption of such remedies and measures as would tend to obviate inflammatory action. And he submitted that, when a cancer was brought in the very earliest stage to the surgeon, it was more judicious to watch it for a time, so as to avoid operating in those cases where, by the peculiar nature of the disease, operation could do no good, and would inevitably appear to the patient and patient's friends to have done harm. The author referred to the valuable statistics of Mr. Sibley and Mr. Morratt Baker as affording us the average duration of life under varying circumstances in cancer; but he thought, nevertheless, the study of individual cases was requisite to be able to enable one to attempt or confidently declare a prognosis—prognosis having often an importance beyond its scientific interest in making provision for the welfare and comfort of the patient.

After a few remarks from Dr. GLOVER and Mr. MAUNDER, the PRESIDENT suggested it might be a good subject to take up for discussion.

*Specimens of Tendon Ligatures.*—The PRESIDENT exhibited some specimens of the kind. It was certain, he remarked, that doubt existed as to the trustworthiness of catgut for the ligature of arteries in their continuity. A material that occasionally failed to arrest the blood-stream for a sufficient time to ensure the cure of an aneurism, could not be recommended with confidence. He hoped a more extended trial would confirm the promise that we had in fine tendon ligatures, that they would resist the solvent action of their surroundings in a wound, so that, although they were eventually dissolved, they lasted longer than catgut. And these ligatures tied better knots than the catgut, and the knots did not slip. Their strength, too, was sufficient; and, as they dissolved slowly, they answered well for sutures, especially where some strain was put on them, catgut quickly yielding under such an influence. The specimens of ligatures handed round had been sent him by Mr. Hulme of Guildford, who had received them from Mr. T. M. Girdlestone, Surgeon to the Albert Hospital at Melbourne. They were extracted from the tail of a marsupial, and were of various sizes as they grew. They had not been split. Mr. Girdlestone said they made very good sutures, but he had not used them on arteries. The natural tendons, however, had been freely used for ligatures. They were simply washed and dried. Before use, they should be soaked in carbolised oil, and Mr. Girdlestone recommended that they should be softened in carbolised water just before use. As the supply of these tendons was distant, and as he (the President) was unable to find any precisely similar, of sufficient length, in this country, he was having prepared ligatures which were made from tendons of the horse. They had the same characters as the tendons from the marsupial.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, FEBRUARY 5TH, 1878.

CHARLES MURCHISON, M.D., D.C.L., F.R.S., President, in the Chair.

*Rupture of the Aortic Valves.*—Dr. BURNEY YEO related the subsequent history of a case of this lesion in a man whom he exhibited at the Clinical Society in May 1874. The man had a loud cardiac murmur, heard first a few weeks after a fall down eight or nine steps, when he had clutched violently at the handrail. He was a healthy fresh-looking man aged 45, and of temperate habits. He had occasionally had some rheumatic pains in his limbs. A loud musical murmur was not only heard all over the chest, but he heard it himself, and it was audible at a distance of three feet from his body. He had no pain, no faintness, and no great dyspnoea. The murmur changed a good deal in character; once it was almost lost, and then again a loud double murmur was heard. In January last year, he was much worse; he had muscular feebleness and impaired sensation and co-ordination, being somewhat ataxic. His heart was hypertrophied, and the area of dulness was very large. In November last, when dressing, he dropped down dead. At this time, he felt so ill that he was dressing to go to the hospital. A *post mortem* examination was held, but the chest only could be examined. The heart was very large, the muscular structure commencing to undergo fatty change, while the aorta was atheromatous. As to the valves, it was found that the anterior segments were separated, and the torn cusp vibrated back and forwards in the blood-current. The duration of the case was three years and a half.—In answer to a question by Dr. Douglas Powell, Dr. YEO said that the pulse was not first aortic and then subsequently mitral, but was an aortic collapsing pulse all through.

*Prostatic Tumours Removed by Lithotomy.*—Mr. BRYANT related two cases where prostatic tumours had been removed in lithotomy.

The first occurred in a man aged 67, who had had a stone for some time. The prostate was enlarged; and therefore the blunt gorget was used. The stone was found to be a large one; but the resistance offered to its removal was unwontedly great. A portion of prostate was found to be grasped by the forceps, as well as the stone. Both were removed. The stone was one inch and a half in diameter, and was a mulberry calculus covered with uric acid. The case did well, and there was no hæmorrhage. The portion of prostate consisted histologically of gland-tissue with muscular fibre. The second case was that of a man aged 70, who had old bladder-symptoms from a calculus. On performing lithotomy, the prostate was found enlarged, and the stone met with unusual resistance to its withdrawal. A portion of the prostate was grasped by the forceps, and on rotating the forceps a prostatic tumour came along with the stone. In this case, also, there was no hæmorrhage, and the case did well. In the second case, it was thought, from there being some cell-structure in the growth, that it was a malignant adenoma; but the after-history disproved this view, there being no bladder-symptoms now.

*Impacted Fracture of Shaft of Femur.*—Mr. BRYANT gave an account of such an injury, occurring to a man aged 83, who fell down some steps on his right knee. The right thigh was swollen and shortened by two inches. The case went on well till uræmic symptoms set in. On *post mortem* examination, the kidneys were found to be suppurating. The femur was found fractured and the proximal end driven into the distal shaft, splitting it to the condyles; the seat of fracture being at the top of the lower third. Impaction might thus take place into the shaft of the bone, and the injury described could only have taken place through a fall on the knee. Extension failed in these cases to make the limb of normal length. There was a danger of over-manipulation.

*The Bacillus of Splenic Fever.*—Dr. EWART described the bacillus anthracis of splenic fever, specimens of which were shown under the microscope. This form of bacterium is a specific organism, which produces certain lesions and results ending in death. In the first specimen were to be seen rods, of which the capillaries and larger vessels were full, so that the animal seems to die of asphyxia. When blood, containing the bacillus anthracis, is put into a drop of water, the rods are seen to elongate into threads. In twenty-four hours, they are minute stakes. The spores of the bacillus develop at a temperature of 82 deg. Fahr. They are small, and escape from the tube in which they form, the tube at times breaking across. They always set up the same results when introduced into the skin. This bacterium is the cause of splenic fever.—The PRESIDENT asked how often these spores could be reproduced from solutions of the mother fluid.—Dr. EWART said three generations could be so produced. The mouse when infected died in three days. Rods only were found in the mouse.—In answer to Sir Joseph Fayrer, Dr. EWART said the fluid used by him came from Breslau, and was taken from the sheep.

*Forms of Cancer of the Throat.*—Mr. LENNOX BROWNE exhibited four specimens, illustrated by drawings and microscopic preparations, of: 1. Primary cancer of the tonsil; 2. Cancer of the tongue, invading the tonsil (living patient); 3. Pharyngo-laryngeal cancer (living patient); 4. Primary cancer of the larynx. He stated that cancer of the tonsil was of extreme rarity, only one case having been brought before the Society; in that instance, the disease had been discovered only after death, following an operation for removal of enlarged cervical glands; and the disease was hardly mentioned in standard works on pathology or surgery. He had in the last eleven years seen six cases of primary cancer of the tonsil, which number, on a low computation, gave an average of one case to about every five thousand patients suffering from throat-diseases. The variety of cancer in this region had been generally stated to be that of scirrhus; but his own experience had lately led him to believe that it was more frequently encephaloid. All his cases had occurred in male patients of between forty and sixty years of age. Probably the greater tendency of females, of cancerous diathesis, to disease of the mammary glands, to say nothing of the greater frequency of cancer in the female organs of generation than in those of the male, accounted for this immunity of women from tonsillar cancer. The patient from whom the first specimen was taken was a man aged 53, and was under observation from September 17th to December 24th, 1877, the day on which he died. His case well illustrated the ordinary signs, symptoms, and course of the disease, namely: gradually increasing swelling of the affected tonsil and faucial tissues around, with corresponding infiltration and hypertrophy of the sub-maxillary and cervical glands; extreme dysphagia, with constant ear-ache, both relieved on occurrence of ulceration, and by hæmorrhage, which are so frequent, and which, as in this case, usually lead to death. Emaciation is also very rapid. This patient lost twenty-six pounds in ninety-eight days, and seven pounds in the last fourteen days of his life.

Relief had been given by removal on two occasions of portions of the tumour by the galvano-cautery loop, and this was the only surgical treatment which could be safely recommended. The second case was even more rare, and was the first he had seen, although he had since learned that his colleague Dr. Llewellyn Thomas, who kindly transferred this patient to his care, had witnessed another similar to it. It was by no means unfrequent for the pharynx and floor of the mouth to be invaded by contiguity of epitheliomatous ulceration; but, in this instance, the disease was actually of the tonsil itself. The patient had suffered from one or two attacks of severe hæmorrhage, and the termination of the case would probably be the same as in that of the former specimen. The only difference clinically was the greater unintelligibility of speech, due to the lingual disease. The third and fourth specimens were shown in connection with each other, to illustrate the two most usual varieties of cancer of the larynx. In the living specimen, it was seen, on admission, to commence on the pharyngeal border of the larynx, and so to press on the right arytenoid cartilage, the action of which was somewhat paralysed, and against the cricoid. The disease had now extended right across the back wall of the larynx, concealing its posterior border, and greatly diminishing the orifice of the gullet; later, the cartilages would probably undergo carious degeneration. In these cases, the disease was almost invariably epithelioma; there might be only slight laryngeal symptoms, but dysphagia would be chiefly complained of, and death would be by starvation. In the other case, the disease had commenced actually in the cavity of the larynx, and was of much greater rarity. Here dysphagia was by no means extreme, and, on *post mortem* examination, the body of this patient was seen to be covered by a good layer of fat; but the laryngeal symptoms were most severe. In conclusion, it was submitted that both these cases illustrated how difficult it would be, by any radical operation, to remove all the disease in this region; and even if the patient survived its immediate effects, how slight was the chance of ameliorating the symptoms or of preventing recurrence.—The PRESIDENT asked if the cancer of the tonsil had been examined microscopically, as the diagnosis of cancer from syphilis was difficult clinically.—Mr. BROWNE replied that such examination had been made; at first it was thought to be scirrhus, now he could only be sure it was a malignant growth. Specimens were referred to the Morbid Growths Committee.—Mr. BUTLIN spoke of a case of primary sarcoma of the tonsil removed by Mr. T. Smith. It was a tumour of the right tonsil. It returned four months after removal, and the glands of the neck were infiltrated. It was again removed, and had not returned. There was no hæmorrhage at either operation, each of which was performed with the *érasateur*.

*Sequel of a Case of Recurrent Sarcoma.*—Mr. NUNN said that, eleven years ago, he removed a tumour, twice the size of the fist, from the shoulder of an old man. A section was submitted to the Morbid Growths Committee, and it was decided it was cancerous in its nature; nevertheless, there had been no return.

*Plugging of Superior Mesenteric and Femoral Arteries.*—Mr. HOWSE exhibited a fresh specimen of ulceration of the bowel, with plugging of the superior mesenteric artery. It occurred in an old woman, who had gangrene of the leg. The coils of intestines could be readily seen through the abdominal parietes. The femoral artery had ceased to pulsate, and, as the patient complained of great pain, the thigh was amputated, and no more pain was experienced. The diarrhoea remained. After death, it was found that the femoral artery was plugged up to the external iliac. The superior mesenteric was plugged by a fibrinous clot. The gut was almost sloughing. The colon was adherent to the small intestine, and a perforation had taken place at this spot. There were scars on the great intestine.—The PRESIDENT asked if the intestinal lesion came first and the plugging after, or *vice versa*.—Mr. HOWSE thought the ulceration secondary to the plugging.—Dr. COUPLAND asked if the gangrene of the leg were embolic. If a portion of the clot in the superior mesenteric got into the aorta, it might be washed into the femoral artery.—Mr. HOWSE said the clot extended into the aorta. The heart and aorta were healthy. She stated that she had passed black stools.

*Caries of Spine.*—Mr. BARKER showed a spine with most extensive caries, taken from a girl aged 15, who came to the hospital on crutches. The abscess which existed was opened antiseptically, but the patient died. The caries extended from the higher dorsal vertebrae down through the lumbar discs. The abscess went down the sheath of the psoas muscle to the thigh. Another abscess was connected with the sacrum, and had sinuses on either side of the perineum. The vertebral discs moved on each other freely. There was right pleurisy. The liver, spleen, and kidneys were amyloid.

*Sarcoma in Muscle of Leg.*—Mr. WALSHAM exhibited, for Dr. Marshall of Nottingham, a tumour in the leg of a female child five months old. There was a swelling in the calf of the left leg till it was twice

the circumference of the right leg. There were no enlarged glands in the groin. A needle was passed in and bright blood followed. The leg was amputated at the knee. The tumour was found to be a spindle-celled sarcoma. The interest lay in the early age at which it had appeared.

**Genital Obstruction of the Common Bile-Duct.**—Mr. MORGAN related a case. It was in a child of healthy parents. The meconium was healthy, and the cord came away normally. Then the child became yellow, was not well; it improved, but grew more jaundiced. There was no enlargement of the liver. The urine stained the napkins. Several cutaneous hæmorrhages took place. The bowels were open, the feces green; there was no bile in them. The child had convulsions, and died. It was a fairly nourished child. The other viscera were healthy but bile-stained. The liver was enlarged; the gall-bladder small; the duct patent, but empty. The canal of the ductus communis choleodochus was obliterated for half an inch. The intestines were collapsed. The friends would not allow any part to be removed. The lesion was rare. The child lived for ten days without symptoms, and died at nine weeks and a half.

#### MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, NOVEMBER 7TH, 1877.

A. RANSOME, M.D., President, in the Chair.

**Removal of Metatarsal Bone of Great Toe.**—Mr. JONES showed a girl, eleven years of age, the metatarsal bone of whose great toe he had removed in August last. The operation was performed for disease of the bone of more than three years' standing. The wound healed in a fortnight, and the patient was now able to walk without any perceptible lameness. The great toe was shortened and retracted nearly to the extent of the length of the metatarsal bone. The false joint had formed between the metatarsal phalanx and the internal cuneiform bone.

**Salivary Calculus.**—Mr. BOUTFLOWER exhibited a salivary calculus, of comparatively large size, obtained from the submaxillary duct of a lady patient.

**Progressive Pernicious Anæmia.**—Dr. SIMON read a paper on progressive pernicious anæmia, and pointed out that there was no pathognomonic symptom of the disease, all the symptoms being merely evidences of an extreme anæmia, and undistinguishable from those produced by anæmia proceeding from any cause whatever. He disputed Lebert's and maintained Addison's claim to priority of description of the disease, and considered several of Lebert's cases to be instances of exaggerated puerperal anæmia. The disease is not confined to one sex, but seems to occur during the period of greatest physical activity; in men, generally between the ages of twenty-five and fifty; and in women, between the ages of twenty and forty. Dr. Simon thought that Dr. Pepper's speculations, as to the part played by the marrow of the bone in the causation of this disease, were negatived by direct recent German researches, as well as by the absence of confirmatory experience from other observers. He thought that, while no positive or peculiar pathological lesions had been discovered, the course of the disease, and its analogy to Addison's disease, pointed to a nervous origin. No treatment has hitherto proved permanently successful: a recent case of recovery under the care of Dr. Bramwell not having, in Dr. Simon's opinion, stood the test of sufficient length of time.

**Hemiplegia, with Enlargement of Paralysed Parts.**—Dr. ROSS read notes of a case of left hemiplegia, of six months' duration. The peculiarity of the case was that the arm, forearm, and leg on the paralysed side measured one inch more in circumference than the healthy limbs at corresponding points. The left half of the chest also measured one inch more than the right. The muscles of the left arm and forearm, and to a less extent of the legs, were the subjects of "late rigidity". The joints of the index and middle fingers of the left hand were swollen and red. Small portions of muscle were withdrawn by Duchenne's trocar from the forearm, and, on microscopic examination, were found to be similar to portions withdrawn from a case of pseudo-hypertrophic paralysis under examination at the time. Dr. Ross pointed out that, so far as could be judged in the absence of a *post mortem* examination, the hemiplegia was caused by hæmorrhage into the right lenticular nucleus, causing interruption of some of the fibres of the internal capsule. This was followed by descending sclerosis of the lateral column of the cord on the opposite side. The affection of the joints of two fingers of the paralysed hand showed that the left anterior horn of grey matter was affected; and the question which arose was, whether the latter affection also produced the pseudo-hypertrophy of the muscles of the paralysed limbs. The similarity of this case to one related by Barth was noticed. In Barth's case, as pointed out by Charcot, the

muscular pseudo-hypertrophy was associated with primary lateral sclerosis of the cord.

**Pseudo-Hypertrophic Paralysis.**—Dr. LEECH showed a boy, aged 7, suffering from pseudo-hypertrophic paralysis, in which the hypertrophy was slight and limited to the muscles of the calves. The lordosis was well marked, and the method of walking and standing very characteristic. Indications of weakness of the lower extremities appeared when the boy began to walk. Although, during the past three years, his power of locomotion had much diminished, he could still walk a few yards without assistance.

#### MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.

WEDNESDAY, DECEMBER 5TH, 1877.

SAMUEL GORDON, M.D., President, in the Chair.

**Alternate Paralysis.**—Dr. GEORGE SIGERSON made an elaborate communication on this subject, illustrated by the details of a case of sensori-motor Y-shaped paralysis in a rural clergyman, aged 65, a man of athletic frame, sanguine temperament, and active habits. The designation *paralysis alterne*, which Professor Gubler gave to a certain class of diseases, characterises with equal fidelity the relative position of the lesion and the effect produced. It has sometimes been translated "cross paralysis" by British authors, but this name does not accurately render the original. Whilst "cross paralysis" simply indicates phenomena of decussation, the adjective "alternate", borrowed from the science of botany, where it marks a mode of phyllotaxis, not only shows that opposite sides of the body are affected, but also that the central lesion operates at different relative heights. On this account, the author preferred the term to the more familiar designation, which may prove misleading by its very simplicity. Several topics of physiological and pathological interest were suggested by the incidents of the case detailed by Dr. Sigerson. 1. The term facial or hemifacial paralysis was ambiguous. It seemed to imply that one side of the face was completely paralysed, whereas the muscles supplied by the trigeminal nerve might be spared. Where facial paralysis was meant to designate paralysis of the facial nerve, he submitted that, to avoid ambiguity, the expression paralysis facialis might be employed. In the present case, the muscles supplied by the trigemini were not only spared, but functionally exalted. 2. The liability of the left eye to hyperæmia of the conjunctiva furnished a pathological pendant to the physiological experiments of Magendie, Snellen, and Schiff. It had been proved that section of the trigemini was not necessarily followed, as at first alleged, by hyperæmia and ulceration of the eye, if only the precaution were taken of keeping it covered. In the present case, of two eyes equally sensitive, one became injured because of the inability to close the eyelids. 3. The closure of the paralysed nostril on inspiration (as mentioned in manuals) was dependent on its form; if normally wide and funnel-shaped, the entrance of a current of air did not necessarily tend to close it. 4. The sense of taste appeared to depend, to some extent at all events, on the lingual branch of the trigemini, inasmuch as its paralysis was accompanied by a diminution of taste, as well as of tactile sense, in the anterior two-thirds of the tongue. 5. The difficulty of which the patient complained in opening his mouth wide, appeared to be due to two causes. a. Abnormal exaltation of the trigemini is similar to what Dr. Sigerson had found elsewhere side by side with paralysis. It seems to constitute what M. Vulpian, in reference to another subject, terms a "balancement". Here it was betrayed by hyperæsthesia of the sensory filaments, and by a quicker response of the muscles to the faradic stimulus than is usual. b. Akinesia of the muscles which serve to open the mouth by depressing the lower maxilla is to be expected when the second branch of the seventh is affected. When the muscles in question were specially treated and their strength augmented, the difficulty in opening the mouth diminished. 6. Part of the deformity noticeable in patients affected by facial palsy is due to the weight of the lax muscles and integument, which tends to drag down the lower eyelid and to deviate the ridge of the nose downwards and towards the paralysed side. Part of it is also due to the surviving action of the quadratus menti and depressor anguli oris, which, being animated by the mental branch of the trigeminal nerve, and no longer equipoised by the tonic force of their antagonistic muscles, depress the angle of the mouth, and give an expression of sadness to the face. Hence, not only is that distortion, which is observable when the patient speaks, due in part to the action of healthy muscles, as has been remarked, but the action of other sound muscles, together with the weight of lax tissue, helps to produce the deformity which is observable when the face is in a state of repose.—A discussion followed the reading of Dr. Sigerson's paper, but no point of general or scientific interest was brought forward.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, FEBRUARY 16TH, 1878.

THE ADMISSION OF LADIES TO THE BRITISH MEDICAL ASSOCIATION.

THE letters which have appeared in our columns from Dr. Wilson Fox, Mr. Lister, Dr. Risdon Bennett, and Mr. Berkeley Hill sufficiently indicate the lively interest excited by the question raised in Dr. Wilson Fox's communication to the Committee of Council, and by the cautious and guarded reply contained in the resolution carried and forwarded to him. What may have been the course of the discussion which led to the adoption of precisely that formula, we have no means of knowing; but, taking it just as it is, we must point out that the position arising out of it is a simple one, and easily admits of satisfactory treatment. The question is one of no very complicated character, although it does not appear to have been fully appreciated by all our correspondents. Dr. Risdon Bennett very clearly points out that the admission of women to the *Medical Register* as qualified practitioners has, with the assent of the General Medical Council, by the influence of Act of Parliament, and by the assistance of the King and Queen's College of Physicians of Ireland, become an accomplished fact. Medical women have also their own medical school, fully equipped with a staff of lecturers chosen from the principal London schools, and a hospital of one hundred and fifty beds in which to complete their practical studies; that question, he points out truly, may therefore be set aside at the present moment.

It is not the matter at issue now, as some writers seem to think, and is not at all raised by the letter of Dr. Wilson Fox or by the answer of the Committee of Council. We have already explained what the facts are in respect to the relation of medical women to this Association, but it may be well to recapitulate them. Two qualified medical women were elected members of the Association: one by the Council of the Metropolitan Counties Branch, and one by the Committee of Council, prior to the Edinburgh meeting in August 1875. At that meeting, the attention of the Association at large was pointedly called to the subject, and a *plébiscite* by circular was ordered to be taken on the question, "Shall women be admitted to the Association as members?" and, out of 4,161 answers received, 3,072 were noes and 1051 ayes.

From the date of the Edinburgh meeting, no women have been proposed or elected, and, of course, would not, or could not, be so in the presence of that decision, although it may possibly legally be necessary and desirable to transform the resolution into a by-law, in order to give it legal effect. The question raised by Dr. Wilson Fox's letter is a retrospective one: What is the position of the Association in respect to ladies who were elected before that decision was taken? To this the Committee answer, that they have no power to prevent these ladies from attending meetings. It is, however, clear enough to us that the members can give them the power which, as a committee, they do not possess; and, under ordinary circumstances, any two members of a voluntary association who found the principle involved in their administration to be negated by the voice of the great majority of that Association, would feel called upon to respect that voice and retire

from the Society which had declared that their presence was unacceptable. Whether the two ladies in question will be advised to take this course we cannot say, or whether, if so advised, they will be willing to take it; but there can be no doubt that a voluntary body has power to make the regulations for its own conduct of business, and we apprehend that the same majority which declared that in future women should not be admitted to the Association, can, if necessary, also declare that the two ladies who happened to be, prior to the resolution, members of the Association, should be informed that their presence at meetings is not desired, and that corresponding instructions have been given. At any rate, it is obvious that it is extremely undesirable that any considerable discussion should arise on a matter of detail after the principle which must govern it has been decided by a large majority. The question is, except as a matter of sentiment, not a very pressing one, as the occasion of offence cannot arise again until the general meeting next August, and it might then be settled by a decision to be taken, of which any of our correspondents may give notice, or as to which the Committee of Council may in the meantime come to a resolution. We would, however, only once more point out that the question is really a very small one affecting only retrospectively the conduct of two ladies in respect to their exercise of privileges against which the general voice of the Association has very decidedly made itself heard. If necessary, a special meeting of the Association could be called for the purpose; but to do so would, we imagine, be to give too much importance to a matter which is in itself intrinsically trifling.

THE GOVERNMENT OF NAVAL HOSPITALS.

WE gladly admit the protest of the *Army and Navy Gazette* against our assumption of their animosity towards the principal medical officer at one of the naval hospitals, which it detects in our recent observations on the subject; but the animus of the writer who instigated the article on "cemetery hay", jam, and the disposal of boatmen at an undesignated hospital, was too palpable not to call for our comment. We desire to go hand in hand with our naval contemporaries in promoting the interests of the service before those of individuals. If, however, the information which led it to believe in the existence of maladministration in one of our large naval medical establishments was in any way correct, why has no inquiry been made? And how is it that one principal has subsequently retired with an accumulation of honours, after a twice repeated extension of his term of office; and that neither he nor the inspector-general who remains in charge of the other large hospital have had any opportunity afforded to them of clearing themselves from the reproach that has been laid upon them; nor has their administration been in any way called in question? Our remarks upon the discipline in hospitals were mainly directed to the management of the patients, and this has elicited the admission that order has been maintained in the wards since the establishments have been under the control of the medical branch of the service; but to allege, as is now done, that there is no difficulty in doing so, is either making light of one of the most important duties of the superintending officers, or must be accepted as a compliment to their administrative capabilities in being able to rule so satisfactorily an average of nearly five hundred patients and their attendants, amounting to sixty or seventy more persons. These attendants are drawn from the same class of men in the service as the patients themselves. The latter, it must be known, are, as to many of them, kept in hospital with trifling wounds, and are otherwise in good health. As none are discharged to their ships until quite fit to resume their duties, there is always a very large number nearly ready for discharge, more or less impatient of restraint, and with spirits and energy sufficient for any amount of mischief, if inclination led or opportunity offered.

But it is not the sick men who, our contemporary says, require to

be controlled; but the large staff. Now, the medical staff of the largest of our naval hospitals consists of eight or nine officers of various ranks, and of ages from thirty to nearly sixty—gentlemen, and bound by the bond of professional brotherhood and etiquette, as well as by the discipline of the service, to yield a loyal and willing obedience to their chief, and to assist him by carrying out all orders for the comfort and well-being of the inmates. The working staff of the administrative department has for its head a civilian officer of long standing, the agent, with his assisting clerks, all of whose duties are clearly defined, so that no superintending officer can well interfere with them. This department is altogether independent of the medical, except as to the superintending officer, through whom pass all orders for payments or issue of stores. Besides the sick-attendants before named, there are from thirty to forty men-servants and labourers variously employed, as the butler, cooks, gardeners, bathmen, etc.; and, lastly, the laundry women and scrubbers, under the control of the matron. As it is not the sick, then, who require control, it is not difficult to see over whom the "watchful eye" and the "sure check" upon irregularities are to be kept. We wish our naval captains a more appropriate and wider field for testing their utility than this. If employment is to be found for half-pay naval captains, every one would wish for them more useful occupation or less undignified sinecures.

#### THE TITLE OF SURGEON.

UNDER the new Dental Bill, which is alleged to have been approved by certain of the examining bodies, it is proposed to confer the title of dental surgeon on every chemist or tooth-puller throughout the kingdom; while, on the other hand, it is to be prohibited in future to surgeons who choose to adopt dental surgery as their specialty, unless they take also the dental licence of one of the Colleges. Now, we would very gladly see the dental profession respectably and satisfactorily organised; but it seems clear that they are here asking too great and quite unnecessary sacrifices. The Parliamentary title of surgeon belongs to members, fellows, and licentiates of the Colleges of Surgeons, and to no other persons. Those persons who take out a dental licence may fairly claim the title of dentists, and that title might properly be reserved for them. The title of dental surgeon should obviously be reserved for those members of the Colleges of Surgeons who take a dental licence. The question is one of common sense. A member or fellow of the College of Surgeons is a surgeon; such a member or fellow, if he take a dental licence, may claim a Parliamentary title as dental surgeon. A licentiate in dentistry may equally claim to have the Parliamentary title of dentist. But it is certainly not desirable to do as is now proposed by this Bill, to treat all licentiates of the future as having a Parliamentary and exclusive claim to the title of dental surgeon, whether they be surgeons or not, and to confound in one category the surgeon who has a dental licence and the dentist who has no surgical licence, giving, moreover, to the dentist who has no surgical diploma the exclusive use of the word (dental) surgeon, against the surgeon who has no dental licence. The immediate effect, moreover, would be that some hundreds of small chemists, quacks, and tooth-pullers, all over the country, would, as was pointed out at the meeting this week of the Parliamentary Bills Committee, have the immediate right to inscribe dental surgeon over their doors, and might possibly write the "dental" very small and the "surgeon" very large, and thus a new set of traps would be laid for the unwary and the uneducated. If the College of Surgeons really sanctioned such a measure, it is to be regretted; but it is not the first time that the Councils of the Corporations have gone to sleep over interests which did not immediately appear to be bound up with those of the Corporations themselves. It will be right to offer a very energetic opposition to this Bill as at present worded. On the other hand, if the promoters are wise enough to distinguish in their register "dentists" and "dental surgeons" in different columns, they will avoid the rock on which their Bill is most likely to split. As it

stands, the Bill cannot pass; and we trust the General Medical Council will interpose at once and aid our Parliamentary Bills Committee preventing this abuse of medical titles.

#### THE REPRESSION OF OBSCENE QUACKS.

WE publish in another column a letter from the Honorary Secretary of the Medical Alliance Association, enclosing a draft of Dr. Lush's Bill for the Amendment of the Medical Acts, so far as relates to the notorious inefficiency of the clause designed to protect the public from the hosts of quacks—many of them of the most dangerous kind—who still prey upon the young and the uneducated of all classes. The preamble of the Medical Act sets forth that it was intended "to enable persons requiring medical aid to distinguish qualified from unqualified persons". Its object has been wholly defeated by the defective wording of the penal clause, which makes the assumption, not of medical titles, but of "registrable" titles only, the subject of penalty. This clause is so badly worded that it has been the subject of numerous conflicting decisions, but has ultimately proved wholly useless as an instrument in carrying out the declared intentions of the Act. The police-magistrates are very sensible of the necessity of this amendment, and the Home Secretary has declared his sense also of the anomaly in wording which has so long left the public and the profession at the mercy of a dangerous class of depredators who hang upon the skirts of the profession, and are among the worst enemies of society. At the last annual meeting of the Association, a resolution was passed declaring the amendment of this clause to be a matter of special urgency, and instructing that, in the conduct of the Parliamentary business relating to medical reform, it should be so treated.

FEVER of a very severe type has appeared in many of the famine districts of Bombay and Madras.

THE annual dinner in aid of the funds of the French Hospital and Dispensary will be held on Saturday next, at Willis's Rooms, when the French ambassador will take the chair.

ONE drop of the oil of eucalyptus, applied on cotton-wool to the sensitive dentine, is alleged to be an excellent local anæsthetic; if so, it should be a valuable remedy for toothache.

DR. GUIDO BACCELLI, Professor of Clinical Medicine in the Roman University, Physician to the late King Victor Emmanuel, has just been decorated with the Grand Order of Saints Maurice and Lazarus, and appointed Honorary Physician to His Majesty King Humbert.

IT is announced that Mr. Mullen, the Herbert Prizeman, who, to the astonishment and much to the delight of the army medical authorities, selected the British Army Medical Service, has now resigned. This is rather a bitter comment, although not an unexpected one, on the extremely unsatisfactory position which the army medical officers hold under the harsh administration of the unification system, and the unsatisfactory arrangements by which medical officers are without due consideration shifted during their term of service from pillar to post, with the ultimate prospect of being turned out of the service altogether at the end of ten years.

#### WORCESTERSHIRE MEDICAL SOCIETY.

THE annual meeting of this Society was held on February 7th. The report of the Committee showed that the work of the Society continued, in this the eleventh year of its existence, to be successfully carried on. The number of members is fifty-six. The ordinary meetings have been fairly attended. Several new standard works have been added to the library, which is now a very valuable one. Mr. Walsh was elected President; Dr. Sherlock, Vice-President; Dr. Strange, Honorary Librarian; Mr. Hyde, Honorary Secretary. A large party of members and friends dined together at the Star Hotel, Worcester, in the evening.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following are the subjects of the course of nine lectures on the Morphology of the Batrachia now being delivered in the College of Surgeons by Professor W. K. Parker, F.R.S.—February 11th: The Meaning, Aims, and Methods of Morphology.—February 13th: Classification of the Vertebrata.—February 15th: Classification and Geographical Distribution of the Batrachia.—February 18th: Metamorphosis of the Batrachia compared with that of other Vertebrata.—February 20th: Structure of the Skull in the Larva.—February 22nd: Structure of the Skull in the Adult.—February 25th: Consideration of the great Polymorphism of the Group.—February 27th: Structure of the Spine, Limb-girdles, and Limbs.—March 1st: The same, continued; Summary; and Conclusion. This course will be followed by one of nine lectures by Professor Flower, F.R.S., on the Comparative Anatomy of Man (in continuation of his course of last year), on Mondays, Wednesdays, and Fridays, commencing on March 4th and ending on March 22nd. In June, Professor T. Spencer Wells will give six lectures, of which the subject will be announced; and Mr. B. T. Lowne will deliver three lectures on the Physiology of Nerve-Stimulation.

## ROYAL FREE HOSPITAL.

THE fiftieth annual meeting of this charity was held last week at the hospital. Mr. James Hoggood presided. In addition to the new wing which we mentioned some time since, the committee have resolved upon erecting another block of the new buildings, which will consist of nurses' room, isolated wards, and board-room. During the year, the hospital has opened its doors to lady medical students, an arrangement having been made that £400 *per annum* be paid to the medical staff for clinical instruction, and an additional £315 annual subscription to the hospital funds by the London School of Medicine for Women. The number of patients received into the in-patient department during the year was 1,369. As regards out-patients, the number in the year, owing to the building operations which had been going on during the year, had decreased to 5,099. Legacies to the amount of £14,037 were announced in the report, and from Hospital Sunday Fund £487 was received, while Hospital Saturday Fund contributed £134. In addition to these amounts, various sums are acknowledged from several city companies, and smaller contributions.

## BRITISH MEDICAL BENEVOLENT FUND.

THE annual general meeting was held on January 10th, 1878, Dr. Birkett in the chair. The report showed that during the year 1877, £1575 were distributed in grants of immediate relief to distressed medical men, widows, and orphans; 169 persons being directly, and about 195 indirectly relieved, making a total of over 360 persons benefited. Eight annuitants were elected during the year. Mr. Webber, who had held the office of honorary financial secretary for several years, being compelled by ill-health to resign, was unanimously elected a vice-president of the Fund, and a special vote of thanks was most heartily accorded to him. Mr. Herbert W. Page, 28, New Cavendish Street, W., was elected honorary financial secretary. Votes of thanks were accorded to Messrs. Churchill for their kindness in supplying a committee-room; to the auditors, Messrs. T. H. Hills and E. Parker Young; to the editors of the medical journals; to Dr. Jonson as chairman of committee; to the treasurer and honorary secretary; and to Sir George Burrows, the president.

## AMBULANCE WORK.

A PUBLIC meeting was held a day or two since at the Pall Mall Restaurant, Regent Street, under the presidency of Sir E. A. H. Lechmere, at which an account was given of the ambulance work of the Order of St. John of Jerusalem. Letters of apology for absence and expressing much interest in the movement were read from the Duke of Manchester, Lord Glasgow, General Viscount Templetown, Lord Percy, the Bishop of St. Alban's, Sir J. McGarel Hogg, General Sir Charles Daubeney, Mr. Archibald Forbes, Surgeon-General T. Longmore, etc. The

chairman said the Order of St. John was a branch of the Order of the Knights of Malta, and the present Order had been established fifty years. The most recent work undertaken by them was that of ambulance aid in times of peace and war, and aimed at creating throughout the country the skeleton of a body which in an emergency might be called into action at the shortest possible notice. Major Duncan gave an account of the manner in which the Order had inaugurated its work, and said that the first meeting in aid of the cause was held in the dark hall at St. John's Gate, when, though the number present was small, no less than £1000 was subscribed. There are at present three centres, viz., Sevenoaks, Woolwich, and Chelsea. In Woolwich, the movement had met with signal success. The movement invited the aid of persons of all classes, both civil and military, and was taken up heartily by the ladies. Mr. Furley then followed with a paper on the general work of the Order.

## WANT OF MEDICAL OFFICERS AT THE CAPE.

ACCORDING to a correspondent at the Cape, the want of army surgeons is very much felt there, and it is stated that there are not even sufficient for all the field hospitals, and the general has authorised the employment of any civil practitioners who can be got.

## THE STUDENTS' WAR MEETING.

A MASS meeting of medical students, on the subject of the war, is reported to have been held last week in Trafalgar Square. We are inclined to think that medical students, as such, had better leave politics alone. As citizens, they have the duty of joining with other citizens in expressing their opinions; but as medical students, they have no such duty, and we deprecate meetings of medical students as such except on medical questions.

## DEATHS IN PUBLIC INSTITUTIONS.

THE Registrar-General reports that there were registered, in workhouse establishments, hospitals, and public lunatic asylums, 11,741, or 9.4 per cent. of the total number of deaths registered in England and Wales during the last quarter of the year 1877, a proportion which showed a marked increase upon that which had prevailed in recent corresponding quarters. In the twenty large towns, 5,878, or 14.6 per cent. of the deaths were registered in public institutions, against 15.5 per cent. in the corresponding period of 1876; the proportion in these towns last quarter ranged from 4.7 and 7.1 per cent. in Oldham and Sunderland to 15.3 per cent. in Manchester and Bristol, and 17.9 per cent. in London. Excluding the twenty large towns, the proportion of institution deaths in the rest of England and Wales averaged 7.0 per cent. Of the deaths in public institutions in England and Wales in 1876, 63 per cent. occurred in workhouse establishments, 27 per cent. in hospitals, and 10 per cent. in lunatic asylums.

## VIOLENT DEATHS.

The quarterly return of the Registrar-General informs us that the deaths referred to different forms of violence, during last quarter, in England and Wales were 4,173, and were fewer than in any previous corresponding period since that of 1872; they were equal to an annual rate of 0.67 per 1,000 persons living, and to 3.4 per cent. of the deaths from all causes. In the agricultural counties of the Eastern registration division, the death-rate from violence did not exceed 0.47 per 1,000, whereas it was equal to 0.90 in Lancashire, 0.70 in the West Riding of Yorkshire, and 0.87 in Durham, where manufacturing industries mainly prevail. In the twenty large towns, the death-rate from violence averaged 0.75 per 1,000; and, while it did not exceed 0.24 and 0.28 in Norwich and Portsmouth, it ranged upwards to 1.04 and 1.21 respectively in Birmingham and Liverpool.

## INQUESTS.

DURING the last three months of 1877, the inquest cases registered in England and Wales were 6,432, and equal to 5.2 per cent. of the total deaths; this proportion scarcely differed from the average proportion in

recent years. In the twenty large towns, the proportion of inquest cases averaged 5.9 per cent., but ranged in the various towns from 2.6 in Oldham and 3.3 in Sheffield and Wolverhampton to 8.6 in Manchester and 9.5 in Nottingham. Thus the proportion of inquest cases was nearly four times as great in Nottingham as in Oldham; and the Registrar-General naturally inquires whether too many inquests are held in Nottingham or too few in Oldham? In England and Wales last quarter, the inquest cases exceeded the number of deaths referred to violence by 54 per cent., and in the aggregate of the twenty towns by 78 per cent.; in London by 86 per cent. and in Manchester by 235 per cent.; whereas the excess of inquest cases upon the deaths referred to violence was but 15 per cent. in Oldham, 17 per cent. in Hull, and 43 per cent. in Sheffield.

#### DEATHS BY MISADVENTURE.

THERE is reason to believe, from the relative frequency of the occurrence of accidents in connection with external washes and powerful medicines at hospitals, that there is much room for improvement in the precautions taken in labelling liniments and other poisonous applications, whether for out-patient or in-patient use. The most recent of the cases referred to was that of Henry Morton, a patient in the Hampstead Small-pox Hospital, upon whose body Dr. Hardwicke held an inquest. The evidence showed that deceased contracted small-pox, and was removed to the above-mentioned establishment. After admission, he was found to be suffering from pleurisy, and Mr. Samuel Bingham, the medical superintendent, ordered an outward application, comprising belladonna, about 10 P.M. on Wednesday last. The nurse, Caroline Cooly, while in the act of attending upon him, heard a summons to open the door of the ward. She hurriedly put down the bottle of lotion on the side-table, and went to the ward door, admitting the visitor. On returning to the bedside, Morton remarked "I have taken what was in the bottle". Cooly immediately summoned assistance, and for four hours antidotes were administered to the young man, but he expired twelve hours after swallowing the lotion. The jury returned the following verdict: "That deceased expired from exhaustion while suffering from small-pox and an effusion into the chest, and the jurors further say that the death took place after taking belladonna by misadventure." It is not stated whether the bottle containing the liniment was a fluted bottle, or whether it was legibly labelled "poison".

#### CÆSAREAN SECTION.

DR. J. BRAXTON HICKS performed this operation on Tuesday night at Guy's Hospital, upon a woman whose vagina was occupied by a scirrhus mass, which involved the rectum and recto-vaginal septum. The placenta was found beneath the line of incision, and the foetal head at the fundus uteri. However, the membranes were reached from the lower end of the uterine wound, and the head seized and brought out first. There was very little hæmorrhage. The uterus contracted firmly after the removal of the placenta. The uterine wound was brought together by interrupted sutures closely placed; and a large catheter was retained in the uterus, passing through the vagina, to prevent accumulations and facilitate injections in case of need. The child, which was slightly premature, was living when last heard of.

#### SMALL-POX EPIDEMIC AT HARWICH.

NEWS of a favourable character has been forwarded by our correspondent at Harwich regarding the progress of the recent outbreak of small-pox there. The hospital has now been open for the reception of patients for six weeks. Sixty-one cases have been admitted. Of these, twenty-five have already been discharged cured; fourteen have died in hospital; and twenty-two, all of whom are in a more or less advanced stage of convalescence, remain in the hospital. Thirty-one cases were admitted the week ending January 9th, eight the second week, ten the third, five the fourth, four the fifth, and three the sixth week. The mortality was greatest amongst the earliest cases admitted, as many as six having died of the first twenty cases, which is in a great measure attributable to want of proper accommodation

before being admitted. The proportion of confluent cases was very large, twenty-five of those admitted being of that character; amongst them being a man who was before deeply pitted with the small-pox, having had a severe attack in infancy. This patient died on the eleventh day. There were four hæmorrhagic cases; two complicated with bronchitis, and one with extensive joint-disease. The other fatal cases were confluent. No case where revaccination has been successfully performed has been admitted to hospital, except one where the disease had been already contracted. Four persons were admitted who had not been vaccinated, but only one died; the other cases, although severe, having terminated favourably. In all the modified cases, the cicatrices of vaccination were well marked. It will be seen that the adoption of isolation is producing good results. The time has been very short, yet the abatement in the disease is well marked; and, if things continue to improve in the same ratio, the people of Harwich will have reason to congratulate themselves on the success of their hospital. There have been three or four cases in the town in the fortnight that have not been received into hospital; but, allowing for those, the diminution in the number is marked.

#### PROVIDENT DISPENSARIES IN BIRMINGHAM.

THE Joint Committee appointed by the Birmingham and Midland Counties' Branch of the British Medical Association and by the Midland Medical Society, to act in the interests of the public and of the profession in reference to the proposed establishment of provident dispensaries in Birmingham, and consisting of forty-eight members chosen in equal numbers by the respective societies, have elected the following officers. *President*: Mr. Sampson Gamgee, F.R.S.Ed. (President of the Branch).—*Vice-Presidents*: Dr. Monckton of Rugeley, and Dr. Sawyer (President of the Midland Medical Society).—*Treasurers*: Mr. Watkin Williams, F.R.C.S. (Treasurer of the Branch), and Mr. Harmer (Treasurer of the Midland Medical Society).—*Honorary Secretaries*: Dr. Savage and Dr. Welch.

#### THE THROAT HOSPITAL.

THE reports published in the daily papers of the late annual meeting of the governors of the Throat Hospital, in Golden Square, gave a brilliant and harmonious view of the proceedings, but omitted all public reference to the recent withdrawal of His Royal Highness the Prince of Wales and other distinguished persons, as the result of a report to which we have already referred. The following report of some of the omitted proceedings is furnished by a gentleman present, who vouches for its moderation and accuracy.

"The annual meeting of subscribers of the Throat Hospital, in Golden Square, was held at the Beethoven Rooms, Harley Street, on Saturday, the 9th instant; the chair being taken by Lord Calthorpe. The reports of the Committee of Management and the Medical Superintendent were read. The former included a lengthy defence of the action taken by the Committee in resisting the efforts made to reorganise the hospital; and reference was made to the inquiry instituted at the request of His Royal Highness the Prince of Wales, and to the subsequent withdrawal of the patronage of the Prince and Princess of Wales, and the resignation of the Marquis of Bute, the President of the Hospital. After other reports and the balance-sheet had been discussed, the Chairman announced that a requisition, signed by twenty vice-presidents and subscribers, had been forwarded to the Secretary, requesting him to convene a special general meeting of subscribers to receive the report of the Court of Inquiry (of which the Duke of Grafton was President), instituted by the late President at the request of the Prince of Wales; and also to appoint a committee of investigation into the causes which had induced their Royal Highnesses the Prince and Princess of Wales to withdraw their support from the institution. Mr. Bowring (a vice-president of the hospital) proceeded to criticise the report of the Committee, pointing out that many of the statements contained therein were not justified by the facts of the case. He was thereupon interrupted by cries of "Order, order", and, after vainly attempting to gain a hearing, he stated that the character of the meeting was very evident. It was quite clear to him that it was composed largely of the relatives and friends of the medical superintendent. He concluded by expressing his astonishment that Lord Calthorpe should place himself in such a position. He then withdrew amid a great uproar. A member of the

Committee of Management expressed some doubt whether the requisition addressed to the Secretary was signed by a sufficient number of subscribers, and asked the Chairman whether, if this was the case, the special general meeting would be called. A subscriber then stated his extreme surprise that the Committee of Management should be anxious to avoid a thorough investigation into the cause of the withdrawal of the Prince of Wales's patronage. On the motion coming forward, that the retiring members of the Committee should be re-elected, attention was called to the fact that the trustees of the hospital consisted of Dr. Mackenzie, his father-in-law, and his own solicitor, who were *ex officio* members of the Committee of Management; and that, in addition to this, Dr. Mackenzie had a brother and four brothers-in-law on the Committee; and an amendment was moved that the name of one of Dr. Mackenzie's brothers-in-law, who offered himself for re-election, should be omitted. The original motion was, however, carried. Amid some opposition, a subscriber then called attention to the fact that, although the Prince of Wales had severed his connection with the hospital seven or eight months since, yet, during the current month, he had received a receipt bearing the name of His Royal Highness as patron. This raised a storm, but no explanation was offered by any member of the Committee."

#### A BATCH OF CENTENARIANS.

ACCORDING to Dr. Bertherand, there are one hundred and sixty-six centenarians in Algeria, thus proportioned: eighty-eight individuals 100 years old, one of 101, seven of 102, nine of 103, fifteen of 104, six of 105, six of 106, five of 107, one of 108, three of 109, eight of 110, two of 111, two of 112, one of 113, two of 114, four of 115, one of 117, and one of 118 years.

#### THE DEATH OF THE POPE.

THE severe illness of the end of last year from which Pius IX was slowly recovering, had left him but little strength to fight against any other complaint. He appeared, however, to be making satisfactory progress, when he was suddenly attacked, on the evening of the 6th instant, with the incipient symptoms of acute pulmonary congestion. He was then thought to be only slightly feverish, and, after going to bed, he slept a little at intervals up to 3 A.M., when his symptoms became aggravated. Some restorative medicine was then given, and he was quiet again for a short time; but, about 5 A.M., he began to be more uneasy, the breathing became much more hurried, and there was a good deal of bronchial secretion, which rapidly accumulated, so that, at 10 A.M., his pulse was nearly imperceptible, though he was quite conscious, and had received the last sacrament and extreme unction. About noon, the breathing became abdominal and the face and extremities livid; and at 3 P.M. he was comatose and in the death-agony, which lasted until a quarter to six. The body has been satisfactorily embalmed, and has been lying in state in the Chapel of the Sacrament at St. Peter's.

#### BURIAL SOCIETIES.

At the Chester assizes, Mr. Justice Lush, referring to the Warrington poisoning case, remarked that, if it were murder at all, it had been induced by the temptation held out by insurance societies to poor people to insure the lives of persons at the low premium of a penny weekly. His lordship said it was a thing which he could not characterise as too mischievous, because the insurer had a pecuniary interest in the death of the person insured.

#### OVARIOTOMY IN AMERICA.

DR. J. MARION SIMS forwards to us from Paris some interesting particulars respecting the late Dr. Peaslee, whose premature death we mentioned last week. We are unable to find space for the manuscript which he forwards us. We gather from it, however, that in the early days of ovariectomy, when it was condemned by the united voice of the profession here and in America, Dr. Peaslee took his stand by Atlee of Philadelphia, and Dunlap of Ohio, in advocating and performing it; and by his lectures, his writings, and his work, he was all-powerful in aiding his co-labourers in the great work of establishing this operation on its present solid basis in his own country. Whatever

Dr. Peaslee did was always thoroughly well done. He filled at various times and in different medical schools the Professorships of Anatomy, of Surgery, of Physiology, and Pathology, of Obstetrics, and last of Gynæcology; and at the time of his death he was President of the American Gynæcological Society, of which he was one of the founders.

#### THE LONDON FEVER HOSPITAL AND ITS PAYING WARDS.

THE annual report of the London Fever Hospital was presented this week, at the annual meeting, by Dr. Cayley. It stated that, during the year, there had been 629 admissions, and that 723 patients had been treated for enteric, typhus, and scarlet fevers in the year, during which there had been "no marked prevalence of fever", and that there had also been cases of rubeola. From the financial report, it was shown that during the year, in consequence of the falling off in donations, attributed in some degree to the collection for the Indian Famine Fund, the Committee had been obliged to sell out a material part of the small funded capital to meet the current expenses, and they looked with dismay upon the future, as the staff of the hospital has to be kept in an efficient state to meet any emergency arising from epidemic. This institution is one of great utility, inasmuch as it affords means of isolating persons suffering from contagious fevers who are not of the pauper class. It includes some paying wards. It is, however, a noteworthy sign in connection with these wards, that the medical attendance is gratuitous. Such wards, therefore, ought not to be used, except for persons little above the pauper class; and we very much doubt whether, when home hospitals shall be established at which each medical attendant will have the right of attending his own patients, on the usual fees, and of making his own arrangements for payment, these paying wards will have any *raison d'être*. If the patients or their friends are made to pay for their board, lodging, and medicine, it is not clear that they should not pay in proportion for their medical attendance, which is an important item in the benefits which they receive.

#### DEATHS FROM CHLOROFORM.

FOR a short time, deaths under chloroform appeared to be growing fewer in proportion as the less dangerous anæsthetic ether, to which we have now for several years persistently drawn professional attention, came more and more into extensive use. Chloroform casualties are apparently, however, just now thickening again. The Liverpool coroner held an inquest, on Saturday, on the body of a sailor named Michael Cain. The deceased met with an accident, and was taken to the Northern Hospital, where it was found that he was in danger of losing his sight. An operation was decided upon, and the surgeons administered chloroform; but in a few minutes the patient died from failure of the heart's action. The jury returned a verdict accordingly, and exonerated the surgeons from blame. We have been favoured with further particulars of this case from Mr. R. Hughes Jones, which we will publish next week.—Another death from chloroform took place at Ancaster, Ontario, a few weeks ago. The patient, an elderly lady, was about to undergo an operation for the removal of a tumour in the axilla. Only a small quantity of chloroform had been given when she suddenly died. Fatty degeneration of the heart was discovered at the *post mortem* examination. The medical men were fully exonerated from any reflection.

#### OXFORD UNIVERSITY.

WE have received this week a copy of the examination papers for the degree of Bachelor of Medicine and for the certificate in Preventive Medicine and Public Health. They reach us at rather an unfortunate moment; for, at another time, we might perhaps have been more disposed to admire the list of examiners and papers, and the pomp with which the list of papers for this examination is published in large print, price one shilling, as though constituting a valuable document for some purpose or other. At the present moment, we are tempted rather

to ask for the benefit of how many is this apparatus collected and this publication made. For the "Certificate in Preventive Medicine", here are ten examiners, headed, of course, by the Regius Professor in his decorative presidential capacity, and including such great outer authorities as Dr. Farr and Captain Galton. We think we remember to have heard that one person presented himself, and that his examination cost a hundred pounds. Where he received his education is, of course, another matter, and one on which we might not be able to express views acceptable to the present advisers of Oxford in the suppression of medical teaching. Only one thing is certain: he could not have learnt much about the subjects of examination in Oxford. As to the examinations for the degree of M.B., we have the same observations to make. The candidate for the final examination is examined in materia medica, pathology, therapeutics, forensic medicine, hygiene, midwifery and diseases of women and children, principles of surgery, clinical examination (at the Radcliffe Infirmary), practical hygiene. It is a strange satire on the "Medical Department" of Oxford that precisely these subjects are utterly ignored in its teaching, and that endowments for the purpose of teaching them, as well as those of anatomy and physiology, including the "first examinations", are applied to any other subjects rather than these. Under these circumstances, we have not derived the pleasure which might have been expected from reading these elaborate examination papers.

#### CLAUDE BERNARD.

OUR Paris correspondent writes under date February 11th:—It is with profound regret I have to report the death of Claude Bernard, the eminent physiologist, which took place last night at his residence in Paris, in the sixty-fifth year of his age. The death of such a man is a real loss to science; his career has been too short for men of his stamp. He was born at St. Jullien, in the department of the Rhone, in July 1813. In 1839, he was an *interne* or hospital dresser; in 1843, he took his degree of Doctor of Medicine, and in 1853 that of Doctor of Science. In 1854, he was appointed Professor of General Physiology, a chair created on purpose for him. In the same year, he became a Member of the Academy of Sciences; and the following year he succeeded his illustrious master, Magendie, as Professor of Experimental Physiology at the College of France, and continued to hold the post till his death. In 1861, he was almost unanimously elected Member of the Academy of Medicine; and in 1868 he succeeded M. Flourens at the Academy of Sciences. In 1869, he was appointed Senator by Napoleon III, and raised to the dignity of Commander of the Legion of Honour. Thus it may be seen that his career, though comparatively short, was a rapid and most enviable one; for few men had acquired such celebrity in so short a time. Claude Bernard may be considered unrivalled as a physiologist; but he was also a great philosopher and spiritualist. In his researches among the circumvolutions of the brain, it was not the soul he sought, for he knew it was not to be found there, it being the invisible and immaterial part of man, and perhaps of animals; but it was its *modus vivendi* with the body. The problem, however, of the manner in which the soul and body are connected was not for him to solve. His experiments on animals, and his researches on the physiological and therapeutic action of certain substances, are well known; and he it was who first made known in Europe the intrinsic properties of curare. Though by no means cruel in his nature, he was greatly in favour of vivisection; and he more than once said that, though the operation might be cruel, it was necessary for the enlightenment of science, which should not be stopped merely on considerations of affected sentimentality. The death of Claude Bernard leaves a great blank, which it would be difficult to fill, for physiology is an ever-extending science; and, if physiologists are not rare, men like the subject of this notice are unique of their kind. The President of the Chamber of Deputies, on the day following Claude Bernard's death, stated that the funeral would be celebrated at the expense of the State.

#### ADULTERATION OF WORKHOUSE FOOD.

DURING the past week, John Adams, a farmer supplying the St. Mary-lebone Parochial Schools, Southall, with milk, was fined at Brentford for the adulteration of the article so supplied by him. The workhouse authorities are rather slow in awaking to the fact that, to a very large extent, they are supplied with adulterated and skimmed milk. That fact was brought before them officially a year since by a series of analyses ordered by the Government, performed by Mr. Wanklyn, and issued in the form of a Parliamentary return for public information. We have supplemented it by showing that the hospitals were equally ill-served. Since this, most but not all of the hospitals have taken means to prevent their contractors from defrauding the patients of their fair share of nutriment. The workhouse authorities generally have not taken the same precautions. It is, however, only fair to say that from the manner in which the milk contracts are given out by the parish authorities, they have no right to assume that they can be supplied with pure milk. The whole question is one which we commend to the attention of the Local Government Board, and especially to Dr. Bridges. It is one of the duties of the inspectors of the Local Government Board to see that the food supplied to the paupers is of good quality and represents the amount of nutriment for which it is set down in the official dietary scales. This duty has been neglected by these officials; it certainly should include an analysis from time to time of the various articles of food supplied in workhouses, and especially also in workhouse infirmaries; for if these were done on a large scale, some strange revelations would be made to the public, and the sick poor would largely benefit.

#### DR. RICHARDSON'S TEMPERANCE LECTURES.

DR. B. W. RICHARDSON gave the first of a series of lectures on Temperance, arranged for the National Temperance League, at Devonshire House, Bishopsgate. After expressing his own strong views in favour of total abstinence, he is reported to have said that he deprecated public conferences of medical men on the alcoholic question, as they were sure to be full of learned disquisition which the public could not understand, and of differences of opinion among the doctors; hence the old saying, "Who shall decide when doctors disagree?" He repeated his conviction that the difficulties of total abstinence were mainly imaginary, and that when they were real they were easily overcome. He believed that before long the whole of the medical profession would acknowledge that the total abstainers were right. The deprecation of public conferences among medical men on the subject of temperance, and the preference for the monopoly of the subject to the public on the part of the learned lecturer is, we imagine, an error in reporting.

#### THE INSTITUTE OF CHEMISTRY.

THE first meeting of this new institution was held under the chairmanship of Professor Frankland, F.R.S., at the rooms of the Chemical Society, Burlington House. The chairman gave an account of the origin of the Institute. He drew attention to the increasing importance of chemistry in relation to the wants of communities, and suggested the usefulness of an institute that should be to chemists what the Colleges of Physicians and Surgeons are to the medical profession, the Institute of Civil Engineers is for civil engineers, and the Inns of Court are to the legal profession. Although the need of experts in connection with water and gas analysis, legal proceedings, and nuisances, was recognised, and the application of chemistry to agriculture and manufactures was known to be of great importance, the suggestion was not taken up in a practical way until the beginning of 1876, when a meeting to consider the subject was held at the rooms of the Chemical Society on April 26th. The Institute is under 30 and 31 Vict. c. 131, s. 23, and has power to appoint examiners as to the fitness of candidates for its membership. Professor Frankland, in the course of his address, drew attention to the fact that under the Pharmacy Act of 1868 no one, not even the President of the

Chemical Society, may call himself a chemist unless he is duly registered as a pharmaceutical chemist. There are already two hundred and twenty-five members and one hundred and forty-two associates, and a fund of over £1000 for the new Institute.

## SCOTLAND.

A FEVER epidemic has broken out at Halbeath, near Dunfermline, and is spreading rapidly. Several deaths have occurred.

THE Senatus of the University of St. Andrew's has conferred the degree of LL.D. upon Dr. W. C. Mackintosh, Medical Superintendent of the Perth County Asylum at Merthly, well known for his researches on British Annelides.

INFORMATION reached Glasgow last week, by a circuitous route, that Dr. John Pinkerton, one of the surgeons who was sent out by Lord Blantyre to attend to the sick and wounded in the Turkish army, has died of typhoid fever at Erzeroum. The deceased gentleman was accompanied to the seat of war by his brother, who, however, returned home some time ago. The letter which announces Dr. Pinkerton's death mentions that fever of a most malignant type is raging in Erzeroum, and that large numbers are dying from its effects.

### FATALITY OF MEASLES.

THE epidemic of measles in Edinburgh still continues to spread. Fourteen deaths were returned as due to this cause last week; twelve of these occurred in the old town. There was no death from fever during the same period.

### THE ROYAL PUBLIC DISPENSARY OF EDINBURGH.

THE Royal Public Dispensary of Edinburgh continues to hold an useful place among the public charities. From the recently published annual report, we gather that during the past twelve months, seven thousand seven hundred and sixty-three persons had been seen and prescribed for or otherwise treated at the dispensary. This number is less than in former years, in consequence of the dispensary having been shut up for three months, during which time the old building had been entirely remodelled, thanks to an opportune legacy of £1000 received from the late James Mitchell of Kincairney. Last year, the institution celebrated its centenary. Two hundred and twenty-eight women had been attended in confinement at their own homes, from the dispensary; upwards of six hundred children had been vaccinated. The alterations in the building had cost £1500.

### ALLEGED FALLACIES OF MILK-ANALYSIS.

AT a monthly meeting of the Kilmarnock Town Council, held last week, the burgh analyst reported that he had, during the quarter ending December 14th, examined fourteen samples of milk, of which four were pronounced genuine, and ten adulterated by the addition of water to an extent varying from 0.2 per cent. to 9.8 per cent.; and two of buttermilk, one of which contained 11 per cent. and the other 19.5 per cent. of added water. Some discussion took place as to the value of the analyses, in which it transpired that one of the dealers, whose milk was reported as containing 4 per cent. of added water, on being remonstrated with, denied the charge and challenged inquiry. The inspector thereupon obtained a sample, milked in his own presence, and sent it for analysis, the result being that it also was reported as containing 4 per cent. of added water. It was explained that prosecutions were raised only in extreme cases. It was agreed that the Sanitary Committee should continue to exercise forbearance in carrying out the provisions of the Act.

### ACTION AGAINST THE MANAGERS OF THE ABERDEEN INFIRMARY.

AN action was recently brought, in the Court of Session, by the Inspector of Poor in the parish of St. Nicholas, Aberdeen, against the managers of the Aberdeen Infirmary, in which he sought to have it found and declared that they, as managers of the Lunatic Asylum of

Aberdeen, were bound to maintain gratuitously the lunatics of the city, in so far as their funds would admit. This claim was founded on a minute of June 14th, 1798, in the original foundation documents of the asylum. The Lord Ordinary, however, gave judgment in favour of the defenders, with expenses, holding that the hospital was founded upon a larger basis, and for the alleviation of the insane in a wider district than the town of Aberdeen.

### THE MILK-SUPPLY OF TOWNS.

THE committee appointed at the recent public meeting in Glasgow, called after the report on the milk-typhoid, to consider the best means of having the city supplied with pure milk, have now invited the co-operation of dairymen, farmers, and others, who may be prepared to furnish such a supply under sanitary regulations and inspections. It is stated, however, that very little can be done in this direction, from the fact that most of the farmers in the vicinity of the city have contracts with dairymen. It is understood that the formation of a limited company for the purpose of securing the end in view is contemplated, on the model of the Aylesbury Dairy Company of London.

### SANITARY TEACHING.

THE increased interest taken in sanitary matters by the citizens of Edinburgh, and which recently led to the formation of the Sanitary Protection Association for the Inspection of Dwellings, has now led to arrangements being made for the systematic instruction of those engaged in designing and constructing. The directors of the Watt Institution have instituted a class of sanitation for the benefit of artisans, clerks of works, and architects' assistants. The course embraces what is usually known as sanitary engineering, as it deals with water-supply and the details of domestic sanitation, but is intended mainly to expound the principles applicable to sanitary arrangements and appliances which ought to govern the execution of work. The directors requested Dr. J. A. Russell to give the first course of twelve or fifteen lectures, delivered twice a week. These lectures were begun last week, with good prospects of success. Dr. Russell apologised in advance for any slips he might make in engineering details, but said that it was more important for his audience that the medical aspects of the questions discussed should be correctly put before them, which an engineer might not do so well. We believe that, with the exception of the lectures to the Royal Engineers at Chatham, this is the first course of technical sanitary lectures delivered in the kingdom.

### BETTER ENDOWMENT OF THE UNIVERSITY OF EDINBURGH.

AT a recent meeting of the Association for the Better Endowment of the University of Edinburgh, a report was read announcing, among other things, two donations for special purposes. One of these was in the Faculty of Law; the other donation is by Dr. John Stark, of Auchtermuchty, who has entrusted the Association with £1400 for the foundation ultimately of a competitive scholarship in medicine, to bear his name. Dr. Stark has for the present retained his life-rent of the fund. The whole arrangements for the foundation of this scholarship, and the terms on which it is to be bestowed, are left in the hands of the Association. The acting committee expressed their approval of the proposed object, accepted the fund, and now hold it on behalf of the Association. A few days ago, the committee received intimation, from the trustees of the late Dr. J. P. Macartney of London, of a bequest by him to the Association of £500, free of legacy duty. The average salary of the old-established chairs is, in the Faculty of Arts, only £250 a year; in the Faculty of Law, £176; and in the Faculty of Medicine, £120. One chair has no salary. Since the last annual report, the following (among other) new foundations in the University have been intimated: 1. The Beancy prize in Anatomy and Surgery, endowed with a sum of £1000 by Dr. Beancy, F.R.C.S.E., Surgeon to the Melbourne Hospital; 2. The Thomson bursaries in the various faculties, ultimately to be twenty in number, founded by the late Andrew Thomson, M.D., Edinburgh, with an endowment which will probably amount to about £13,000.

## IRELAND.

DR. CHARLES GRAHAM, late House-Surgeon to the Convalescent Home, died recently in the Belfast Royal Hospital from typhus fever. The funeral took place last week, and was numerously attended. Behind the hearse walked the medical staff, several professors of the Queen's College, the house surgeon, and a large body of students, as a mark of respect to the deceased.

## THE REGIUS PROFESSORSHIP OF PHYSIC.

DR. ALFRED HUDSON, Physician to the Queen in Ireland, and ex-President of the Dublin Branch of the British Medical Association, has been nominated, by the Academic Council, Regius Professor of Physic in the University of Dublin. The salary of the professorship has been reduced to £100 *per annum*, being the same as that of the Regius Professor of Surgery.

## THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

IN answer to a petition of the King and Queen's College of Physicians, the Lord Lieutenant has signified that he sees no objection to grant them a supplemental charter, enabling them to institute an order of members, and also permitting the election of fellows by ballot. The College met yesterday (Friday) to consider the details of the supplemental charter.

## THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

LAST week, Dr. T. H. Purdon presided at the annual meeting of the Belfast branch of the Royal Medical Benevolent Fund Society of Ireland. Dr. W. Arnold, honorary secretary, read the minutes of the previous meeting, which were confirmed. The financial statement, submitted by Dr. Browne, J. P., was adopted. A deputation, consisting of the President, Dr. Browne, Dr. Wilberforce Arnold, and Dr. Moore, was appointed to represent the branch in Dublin at the annual meeting of the parent society, to be held in June; and auditors, honorary office-bearers, and a committee of management, were appointed for the ensuing year. This society has already accomplished a vast amount of useful work, and continues to receive the adherence of a large number of members of the medical profession. The society deserves the sympathy and support not only of the members of the profession, but of the public generally, who are largely benefited by the frequently badly remunerated services of professional men.

## WATERFORD DISTRICT LUNATIC ASYLUM.

WE are glad to state that Dr. Ringrose Atkins, Assistant-Medical Officer of the Cork District Asylum, has been appointed resident Medical Superintendent of the Waterford Lunatic Asylum. Dr. Atkins is a Master of Arts, Gold Medallist, and a graduate in Medicine of the Queen's University in Ireland, and the author of various contributions relating to mental affections. The appointment is one which will be regarded with satisfaction, and the Government have made an excellent selection.

## SMALL-POX AT HOWTH.

AT a meeting of the guardians of the North Dublin Union, held on the 6th instant, a communication was received from the Local Government Board, suggesting that, if this disease continued to spread at Howth, it would be advisable to use the Cholera Hospital for the reception of patients.

## THE PUBLIC HEALTH ACT.

A SPECIAL meeting of the Town Commissioners of Ballinasloe was held last Monday to consider a communication from Mr. Gray, M.P., Chairman of the Public Health Committee of the Corporation of Dublin, in reference to the new Public Health Act. Mr. Gray stated that the Act of 1874 deprived town commissioners, in towns with a population under six thousand, of their jurisdiction as the sanitary

authority; that the same arrangement existed in the present Bill, whilst no such exclusion existed in England. The matter having been discussed, it was unanimously resolved that a memorial should be presented in favour of altering the objectionable clause and transferring the authority to the Commissioners. The Bangor Town Commissioners have also approved of the proposal of Mr. Gray, who intends moving an amendment to that effect in Parliament.

## SMALL-POX IN DUBLIN.

WE regret to learn that a serious increase has taken place in the number of persons attacked by the present epidemic, and that it has spread from the city to some of the country districts. There are at present, we believe, over thirty small-pox patients in the Cork Street Fever Hospital, and about half as many more in the Hardwicke.

## THE ADELAIDE HOSPITAL.

MR. WALSH, as we announced a fortnight ago, having resigned the surgeoncy to this hospital, has been unanimously elected its consulting-surgeon. The Managing Committee, at their last weekly meeting, unanimously adopted the following resolution:

"The Committee, having received the announcement of the retirement of Albert J. Walsh, Esq., F.R.C.S.I., Surgeon to the Adelaide Hospital, cannot accept his resignation without expressing their strong sense of the valuable and energetic services he has rendered to the institution, and their great regret that he has found it necessary to withdraw from the position he has so long filled with such earnestness, kindness, and ability."

Mr. M. A. Ward, one of the numerous candidates for the vacant surgeoncy, has resigned his position as assistant-surgeon of the hospital, because, as we are informed by a contemporary, "he had reason to believe that the appointment of a young gentleman, now resident in North Wales, had been decided upon by the ruling party in the medical board". However this may be, the medical board have decided not to appoint another assistant-surgeon. The students of the hospital have presented Mr. Ward with a flattering address on his retirement. The election to the surgeoncy will be in May.

## SCIENTIFIC LECTURES.

THE second lecture of this year's course of annual scientific lectures in the King and Queen's College of Physicians was delivered on Monday, February 11th, by Dr. Walter Smith. After adverting to the principal reasons for the pre-eminence now accorded to the galvanic currents, the lecturer referred to the methods followed in the application of galvanisation, and the opinion was expressed that, from a clinical point of view, far less importance attaches to the influence of the direction of a current than is often taught. The lecturer next discussed the questions of the direct action of electric currents upon the central nervous organs, and the arguments were detailed, which demonstrate that it is possible to pass a galvanic current directly through the brain and spinal cord; and that the intensity of the current is greatest in the right line joining the two poles. In reference to galvanisation of the cervical sympathetic, Dr. Smith endeavoured to show that, as matters stand at present, the gravest doubts beset the possibility of directly irritating the sympathetic to any purpose, as well as the results to be gained from such a procedure under physiological and pathological conditions. A summary of the principal relations of the motor system to electricity was given, and the lecturer then proceeded to treat of the applications of electricity to diagnosis and prognosis. His remarks referred to four groups of cases: *a.* Central cerebral affections; *b.* Central spinal affections; *c.* Peripheral nerve-lesions; and *d.* Myopathic lesions. In relation to spinal affections, attention was called to Charcot's recently published views, as affording a clue to the seemingly perplexing diversities met with in the course of electrical examinations. The concluding part of the lecture dealt with the modes in which the beneficial action of electricity is exercised. These were grouped under four heads: 1. Counterirritation; 2. Modifying and sedative action; 3. Direct and reflex stimulation; 4. Trophic influence.

## PARLIAMENTARY BILLS COMMITTEE.

At a meeting of the Parliamentary Bills Committee held on Tuesday, the 12th instant, at the offices of the Association, present, Mr. Ernest Hart (Chairman), Mr. Sibley, Mr. Holder (Hull), Dr. Grigg, Dr. Henry, Mr. Alford, and Mr. Nelson Hardy,

The minutes of the previous meeting were read and confirmed.

The CHAIRMAN reported progress on the subject of the inquiry into the amendment of the coroner's court, and mentioned that Sir Robert Christison, Dr. A. S. Taylor, and others, had forwarded documents for the information of the Committee.

It was ordered that the memoranda and correspondence relating to the subject be reprinted for circulation among the Committee and others interested in the subject.

*Dental Practitioners' Bill.*—The Dental Practitioners' Bill was considered. After much discussion, it was moved by Dr. GRIGG and seconded by Mr. NELSON HARDY:

"That this Committee is of opinion that the title of surgeon should not be conferred by law on any others than Members and Fellows of the College of Surgeons.

"That the clauses of the Dental Registration Bill which provide that registered surgeons should not be entitled to call themselves dental surgeons, and that licentiates in dentistry in the College shall be so entitled, are opposed to the best interests of the public and the profession.

"That the Committee recommend that this Bill be so modified that the title of dental surgeon in future and in respect to practitioners not now on the *Register* shall be restricted to Members and Fellows of the College of Surgeons, and that persons holding the licence of any college in dentistry shall be registered only as dentists, and not entitled to use the appellation of surgeon."

Mr. SIBLEY moved an amendment in favour of confining the title of dentist or dental surgeon in future to those who had obtained the licence in dentistry of the College of Surgeons.

The amendment was not seconded.

Mr. HART moved that Dr. Grigg's resolution be amended by adding, after the words "Members and Fellows of the College of Surgeons", in the second paragraph, "also the licentiates in dentistry".

The amendment was carried, and being then put as a substantive motion, was also carried, with one dissentient. The effect of it is to recommend that all persons holding a licence in dentistry should be entitled to be registered as dentists, and that surgeons taking licences in dentistry should be registered as dental surgeons, but that no persons who are not surgeons shall be entitled to call themselves so.

*The Medical Acts Amendment Bill.*—The CHAIRMAN said that on the table and in the possession of the Committee were two Bills—one by Dr. Lush and the other by Mr. Errington—relating to the amendment of the Medical Act; but he had always advised the Committee, since the institution of the Medical Reform Committee, to leave the consideration of such Bills for the amendment of the Medical Act to that Committee, and he now repeated that advice.

Mr. HOLDER and Mr. SIBLEY, however, expressed their objection to that course.

Mr. HARDY pointed out that Dr. Lush's Bill would, if it had effect, carry out the precise instructions conveyed in the resolution at the General Meeting at Sheffield; and, in consequence of the correspondence which had passed between Dr. Waters of Chester and Mr. Carpenter, the Secretary of the Medical Alliance Association, which had promoted this Bill, he felt bound to urge that the Committee ought to take cognisance of Dr. Lush's Bill, which he believed to be a good one, and in accordance with the resolution passed at Manchester, and he believed with the general feeling of the Association.

The CHAIRMAN said, having stated his views, he could not pretend to overrule what appeared to be the unanimous wish of the Committee.

Mr. SIBLEY stated that the insufficiency of the existing law, in failing to enable the public to distinguish between quacks and qualified practitioners, and the consequent injury, both to the public and the profession, had been brought prominently under his notice, in consequence of a recent case at a metropolitan police-court, in which the magistrate had acquitted him with the imperfectness of the law with regard to his inability to afford that protection to the public, which the preamble of the Medical Act showed that it was designed to afford. In this case a man with a bogus diploma, carrying on very objectionable proceedings, had escaped all punishment, and was pursuing his practices with impunity.

Mr. HARDY stated that the Home Secretary had, last year, expressed a strong opinion that such a state of law should not be allowed to con-

tinue. He stated this as a distinct grievance, quite apart from any other.

Mr. HOLDER (Hull) concurred, and concluded his observations by moving that this Committee approves of the Bill introduced by Dr. Lush, under the title of the Medical Acts Amendment Bill, and recommends it to the branches, for their approval and support, and that copies of the Bill be accordingly forwarded to the secretaries and presidents of the branches.

This motion was adopted; and the proceedings terminated.

## ASSOCIATION INTELLIGENCE.

## METROPOLITAN COUNTIES BRANCH.

AN ordinary meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesday, February 27th, at 8 P.M.; when Mr. T. HOLMES, F.R.C.S., will read a paper on Provident Dispensaries, to be followed by a discussion.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*  
W. CHAPMAN GRIGG, M.D. }

London, February 7th, 1878.

## STAFFORDSHIRE BRANCH.

THE second ordinary meeting of the Session will be held at the London and North Western Hotel, Stafford, on Thursday, February 28th, at 4.30 o'clock P.M. The Chair will be taken by Dr. Arlidge.

Members wishing to read papers or show specimens are earnestly requested to communicate at once with either of the Secretaries.

VINCENT JACKSON, } *Honorary Secretaries.*  
J. G. U. WEST, }

Wolverhampton, February 12th, 1878.

## LANCASHIRE AND CHESHIRE BRANCH.

THE first intermediate meeting of this Branch will be held at the Town Hall, Oldham, on Tuesday, March 5th, at 3.30 P.M.

Dr. W. H. Broadbent (London) has kindly consented to read a paper on the Mechanism of Speech and Thought as illustrated by Pathology.

Members wishing to read papers or to exhibit specimens are requested to communicate with the Honorary Secretary as soon as possible.

Dinner will be provided at 6 o'clock.

D. J. LEECH, M.D., *Honorary Secretary.*

96, Mosley Street, Manchester, January 31st, 1878.

## THAMES VALLEY BRANCH.

THE next meeting of the above Branch will take place at the Griffin Hotel, Kingston, on March 14th, at 5 o'clock.

Members who may be willing to read papers are requested to communicate with the Honorary Secretary as soon as possible.

There will be a dinner after the meeting (7 o'clock) at the above hotel. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Honorary Secretary.*

Kingston-on-Thames, February 12th, 1878.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH:  
SPECIAL MEETING.

A SPECIAL general meeting of the Branch was held in the Queen's College, Birmingham, on January 31st, called, in obedience to a requisition, "to consider the position of the profession in reference to the establishment of provident dispensaries in Birmingham". Present, Mr. SAMPSON GANGE, President, in the Chair, and about one hundred members and visitors.

The following resolutions were carried unanimously.

"1. That the rules of the Birmingham Provident Dispensary, and the letter from the honorary secretaries of the proposed institution (January 3rd, 1878), be referred to a Special Committee of this Branch of the British Medical Association; and that it be an instruction to such Special Committee to take such steps as they may deem necessary in the twofold interest of the public and of the profession, and to report.

"2. That the Special Committee on Provident Dispensaries consist of the following gentlemen, with power to add to their number: Mr.

Archer, Mr. Bailey, Mr. Bartleet, Dr. Bassett, Dr. B. W. Foster, Mr. Gamgee, Mr. W. C. Garman, Mr. J. Garner, Dr. Hickinbotham, Dr. Johnston, Mr. Mabery, Dr. Monckton, Mr. Newnham, Mr. Oakes, Mr. O. Pemberton, Dr. Russell, Mr. L. Owen, Dr. Savage, Dr. Thompson (Leamington), Dr. T. Underhill, Dr. Vinrace, Dr. Wade, Mr. W. Williams, and Dr. Welch.

"3. That the best thanks of this meeting be and are hereby tendered to the Council of the Midland Medical Society for their valued offer of full and hearty co-operation on behalf of the members of that Society; that such offer is cordially reciprocated; and that it be a recommendation to that Society to consider the propriety of appointing a Committee to act with the Special Committee appointed at this meeting in the matter of provident dispensaries.

"4. That the sum of £10 be placed at the disposal of the Special Committee.

"5. That this special general meeting be adjourned to the call of the Chairman."

## CORRESPONDENCE.

### THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

SIR,—I have been waiting with some interest for the appearance in the official columns of the JOURNAL of the report of the proceedings of the Committee of Council of the meeting of January 9th last; for they included subjects of great importance to all the members of the Association, to some of which it has seemed to me desirable that general attention should be directed. To my surprise and disappointment, I have looked in vain for the report of the proceedings until this time. They appear in the last JOURNAL (February 9th), exactly one month after date. I have not only to complain of this delay, but I have to add the still more serious complaint that the report is so abbreviated, and is so marred by large omissions, that it gives no adequate idea of the actual proceedings; and this makes it extremely difficult for me to bring under the notice of our associates some of the questions arising out of those proceedings, which may with great advantage, I think, be submitted to immediate discussion.

I. I take first of all Dr. Wilson's Fox's letter on the admission of ladies to the meetings of the Association, and the answer given. To this an amendment was moved, seconded, and discussed, of which no notice whatever appears in what purports to be the official report of the proceedings published in the JOURNAL. Thus there is omitted the due intimation to members that there were those on the Council who did not think the answer given to Dr. Fox adequate to the occasion. The delay in the publication and the omission in report are here, I think, both open to censure. In consequence of the delay, Dr. Wilson Fox's letter of resignation actually appeared in all the medical papers (including our own) before the publication of the resolution to which it was an answer; and, in consequence of the omission, the inadequacy of the reply pointed out in Professor Lister's very pertinent letter appears to be unfairly exaggerated.

I see that our editor appends a note of explanation to Professor Lister's letter, which *post factum* supplies the gap. Is this an official authoritative statement, or the mere private opinion of the editor?

II. The next important item in the report of the proceedings is a long and formal resolution setting forth and approving the terms of the lease of premises in the Strand at a yearly rental of £320, followed by another announcing in detail the insurance of the above premises, together with the amount of a year's rent: a considerable display of minute business care. Could any one have supposed from this the actual facts, which are, that the Committee of Council also decided at this meeting, without consulting or even informing the members, to take upon the Association the business of printers; to expend £1,000 of the funds of the Association in alterations and structural repairs of these premises; besides having in contemplation the expenditure of about another £1,000 in the purchase of printers' material and machines, shop and office fittings and furniture? So important and serious a step and so large an outlay might with advantage, I think, have been submitted for the opinion of the members at large—if necessary, at a special general meeting—before it was adopted and put in force. In any case, I am unable to understand the propriety of arranging the report of its proceedings published in the JOURNAL in such a manner as to set forth in great apparent business detail, only the ordinary fact that a house is to be rented (as at present) and to omit altogether the much more important fact that the Association is about to take up the trade of printing, and especially that it is going

to expend £2,000 of its moneys in house-repairs, fittings, and type. Some satisfactory explanation of the reason of this omission is, I think, fairly due to the members of the Association.

I am anxious that the whole matter should be fully put before and considered by the members, before it is too late for them to express their views for the guidance of the Committee; because, as a Secretary of the Metropolitan Counties Branch recently entering upon office, I learn now that, prior to my accession to office, the Council of the Branch had under consideration a proposal for providing a reception-room for medical visitors to London.

Moreover, at a meeting of the Council of the Branch held three weeks ago, a resolution was unanimously carried, suggesting to the Committee of Council to provide a central office for the use of members of the Association visiting London; and a strong feeling was expressed by some of the most eminent members of the Council, that the central office should be of a kind and in a position suitable to a great professional Association, and not a mere appendage to a printing and publishing office.

I am personally cognisant of an excellent printing and publishing office close to that now selected, and in the same thoroughfare, at a rental, not of £320 *per annum*, but of only £200 a year, and not requiring one shilling of outlay for repairs, etc., such as those on which it is now proposed to expend £1,000 of our money, with immediate possession, entailing no loss of rent during structural alterations and repairs, which, in the present premises, will be a serious item. I am acquainted also with excellent premises in Spring Gardens, Charing Cross, which could be secured at a moderate rent, and which are in good order, which would afford an excellent house and central office for the Association and for the meetings of its Committee of Council, with reading and meeting rooms for its members worthy of a scientific body of gentlemen, who may, I think, reasonably object, as some of our members have already objected to me, to being relegated, as the result of so great an outlay as that now proposed, to a back room over a printing-office.

What I wish especially to call attention to is that, by the omission of the published report of proceedings, essentially important facts, to the welfare of the Association at large, are held back from the knowledge of the members, from whom most valuable expression of opinions might be expected on so vitally important a subject as this.

III. We read next, in the published proceedings, a bare statement that—"The minutes of the Habitual Drunkards Committee were read, and an amendment was moved. Resolved: That in the event", etc.

Irrespective of the defective wording of this minute (which leaves it doubtful whether the amendment moved was or was not the resolution carried), I must here again ask, Why are the minutes so read omitted from the report? Is not this a matter of public interest to all the members? Have not all the members of the Association a right to know at the time what the Committee proposes? Will not, whatever is done by it, be done in the name and with the influence of the Association at large? Why, then, is the knowledge of these views withheld in the meantime from the members?

IV. Finally, I am greatly struck with the fact that all mention whatever is omitted from the report of the proceedings of a most important series of regulations adopted for the general conduct of the annual meetings of the members, and dealing with the rights of members at these meetings. One of them especially is of a character which, I fear, will be found to abrogate a primary and important privilege of members, heretofore in force, and to interfere with the power which they have hitherto possessed of moving resolutions at the annual meetings. I earnestly trust that these regulations will not be withheld from discussion, and I suggest that they be at once restored to what purports to be the report to the members of the proceedings of the meeting.

I claim permission to ask, through the medium of the JOURNAL, of my fellow-Secretaries of Branches and the members of the Association generally, whether they approve of the way in which the proceedings of the Committee of Council are published, or whether they share generally the views which I have expressed.

I claim permission also to ask, in the same manner, the President of Council to state, for the information of my fellow-members in the Association, (1) whence the great delay in the publication of these most important proceedings; (2) by whose authority the omissions were ordered; (3) whether he will not at once direct that the Secretary publish in the official column of the JOURNAL a fuller and more complete report of these proceedings, the most important parts of which are omitted in what has been published last week.

Apologising for occupying so much space,

I am, sir, yours truly, W. C. GRIGG, M.D.,  
Honorary Secretary Metropolitan Counties Branch,  
6, Curzon Street, Mayfair, February 9th, 1878.

## THE ADMISSION OF WOMEN TO THE MEMBERSHIP OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—The position of the British Medical Association with regard to female medical practitioners, as shown by the communications of Dr. Wilson Fox and Mr. Lister, compels me to ask permission to express very briefly my views on the subject. I have been so anxious to avoid giving, even in appearance, any ground for the assertion, often made, that our profession is actuated by an illiberal protection spirit of trades-unionism, that I have hitherto abstained from taking any public part in the discussion of the question of admitting women to the ranks of the profession. But, in the General Medical Council, and in the various and protracted conferences in which I have for many years taken an active part, I have always and strenuously opposed mixed medical education of the sexes, and the admission of women to our medical corporations. When, however, it appeared that public opinion was largely in favour of granting to women the opportunity of earning a living as medical practitioners, it did not appear to me right to refuse them their urgent demand for admission to the *Medical Register*, however undesirable, in my opinion, for their own sakes such a step might be. It must now be assumed that a certain number of women will enter the ranks of the medical profession as legally qualified practitioners. How many will avail themselves of this privilege, remains to be seen. For the credit of British women, and our general social comfort and well being, it may be hoped, and confidently expected, that the number will be few.

The question for the male division of our profession now is, What shall be their relation to the female division? Are we to imperil the efficient working of our educational arrangements and medical institutions, founded and adapted to supply the public with twenty thousand well-educated male practitioners, for the sake of twenty, or say even one hundred women? Are we to deter the best class of our medical students from entering our schools, by compelling them to pursue their anatomical and physiological studies side by side with women? Are we to taboo certain subjects of discussion in our medical societies, or compel a certain number at least of our associates, even at the risk of being considered squeamish, to vacate their seats, for the sake of the advantage to be obtained from the acumen and ready criticism of a certain number of female adjoints? To these and many similar queries an answer must now be given by the profession; and I, for one, must reply in the negative.

The admission of women to the register of legally qualified practitioners being conceded, there will not, I trust, be any lack of chivalry manifested by the male division towards their fair competitors, nor any petty obstacles thrown in the way of their success. But their educational requirements must be supplied by their own exertions, with such aid as they will doubtless be able to induce the public to afford them. Hospitals and schools must be provided for them, where their education can be carried on with the least detriment to their own character, and without endangering existing institutions, established for the professional education of men and the good of the State. The public advantage to be derived from the creation of female doctors is, as yet, too problematical and uncertain to justify the risk of subverting existing institutions of vital importance to our profession, and essential to the welfare of the community. That such a risk is not imaginary, the present position of the British Medical Association is a sufficient proof. A disruption of this, our largest and most prosperous medical association, is inevitable if its council determine that females are to be admitted as members. Such would also be the effect of any similar determination in the case of any of our large medical societies. It must be left to each man's own judgment whether he can, with propriety and comfort to himself and with due regard to the welfare of the patient, join in medical consultation with women. But the conduct of the business of our public bodies must be regulated by what, in the estimation of the majority, is consistent with decorum and moral propriety.—I am, Sir, yours obediently,

JAS. RISDON BENNETT.

22, Cavendish Square, February 13th, 1878.

SIR,—The acknowledgment of the Council of our Association that it is incompetent to prevent the admission of women to the membership of our Association, after a great majority of the members had expressed themselves adverse to such additions to their body, shows that legislation on this point is needed. Now that the letters of Dr. Wilson Fox and Mr. Joseph Lister have directed the attention of the Association to the consequences that admission of women to the British Medical Association entails, it is more than ever incumbent on the Council to call upon the Association to discuss the matter, and legislate in such wise that the laws shall accord with the general opinion of the Associa-

tion. A considerable body—probably a majority—believe that the interests of society are best served by preventing public discussions of medical topics between the sexes. Others think that this drawback may be counterbalanced by the advantages to society that follow the removal of sex from the disqualifications for practising medicine and enjoying all privileges of medical practitioners, among which the full enjoyment of the membership of our Association is no mean one. It would appear that the general opinion is against the admission of women; and therefore it is only fair that, before more are admitted to our body, this question should be formally discussed and settled in accordance with the prevailing opinion, whatever that may prove to be. Contravention of the general opinion of the Association is not to be tolerated simply because the Council has no legal power to prevent it. For this reason, I have no doubt that the JOURNAL will speedily report that the Council is proceeding with due despatch to bring the question before the Association.—I am, sir, etc.,

Wimpole Street, February 9th, 1878.

BERKELEY HILL.

## THE STUDY OF MEDICINE AND NATURAL SCIENCE AT CAMBRIDGE.

SIR,—Among the recent changes which have contributed to facilitate the pursuit of natural science and medicine at Cambridge, and the obtaining degrees in medicine and surgery, is the regulation permitting the "previous examination" in classics and mathematics to be passed in the first term of residence, instead of, as formerly, in the fourth term, so that the student who accomplishes this is enabled to devote all the remainder of his time in the University to natural science and medicine. Many of those who came up last October, all those who were well prepared to come up, took advantage of this regulation, and are now at work at chemistry and the other preliminary medical subjects. I would be glad to call attention to a further step which has been taken in the same direction, by a regulation permitting the examination in classics and mathematics to take place through the Cambridge senior local examination, or the higher local examination of the Oxford and Cambridge schools board examination, before the University course has commenced. Thus the student may obtain the requisite certificates (the certificates which are accepted in lieu of the previous examination); may register as a medical student; and may, immediately on coming to the University and through the whole time of his residence, devote himself to natural science and medical subjects. He has the advantage of beginning when the courses of instruction, for the most part, commence, viz., in October, and he can obtain his degree in medicine at an earlier period. The examinations for these certificates are probably somewhat more difficult than the previous examination, and demand a good knowledge of the subjects required; not more, however, than a lad who has been well trained at school should be able to show at the age of seventeen, which is a very good age to come to the University. Any period which may intervene between the obtaining the requisite certificates, and the commencement of residence at the University, will be well spent in the study of physics, chemistry, or botany.

Information respecting these examinations, the previous examination, and other points, may be obtained through the *Students' Handbook to the University of Cambridge*, published by Messrs. Deighton, Cambridge, price 1s. 6d.

By taking the course thus suggested, the well educated and industrious student may, very well and at moderate expense, pass through the University, and obtain the B.A. and M.B. degrees by the age of twenty-two.—I am, etc.,

G. M. HUMPHRY.

Cambridge, February 8th, 1878.

## MEDICAL EDUCATION AT OXFORD.

SIR,—Your correspondents, Dr. William M. Ord and "M.D. Edin.", have raised in the discussion concerning medical education at Oxford a side-issue which, I hope, may not be allowed to distract attention from the real matter in hand. The object of both these gentlemen is to express their high estimation of the merits of the young men who come from Oxford to London; but one may ask, as "M.D. Edin." himself seems inclined to do, "What has this to do with the question of the desirability or urgent need of proper organisation of the medical faculty of Oxford?" Dr. Ord appears to think that it is a proper and satisfactory function for the richest university in the kingdom to keep young men until they are old enough to set an example of manners and industry to the medical students of a London hospital. No doubt elderly students, who have been matured by the prolongation of school-boy life at Oxford, are less troublesome in some ways to their teachers than the lads of seventeen or eighteen who form the majority of London first-

year students. But I am unable, after an experience of some years in teaching both London and Oxford students, to admit that there is any preference on the score of good manners, good feeling, or hard work, to be given to the Oxford undergraduate. The more extended study of the preliminary subjects of medical education by the students of those London schools where these subjects are not sufficiently taught, would render them as amenable to further instruction as the Oxford men are now found to be by Dr. Ord and "M.D. Edin." This appears to me to be the practical conclusion from the observations of those gentlemen, and certainly not that Oxford is to eject her students of medicine, with their education only just initiated, in order that they may form among the London students an "aristocracy" possessing "the invaluable culture and refinement of academic life". The introduction of these phrases into the question is instructive, as illustrating what I venture to pronounce a delusion with regard to the results of residence at Oxford and Cambridge. A few of our best men (on the average four annually), necessarily either men whose exceptional ability has gained for them college-pensions, or men whose homes have the social advantages of wealth, study medicine in London after leaving Oxford. Only men thus fortunately placed in regard to pecuniary matters can afford, whilst things are arranged as at present, to pass through the preliminary three or four years' residence at Oxford before commencing distinctly medical study. It is a mistake, therefore, to attribute the exceptional abilities and the culture of these gentlemen to any specific virtue of academic life. Here, as very commonly elsewhere in reference to the same matter, there seems to be a confusion of *post hoc* with *propter hoc*. I confess that my most ardent desire is that the work of Oxford as an university may, ere long, cease to be restricted, by misguided friends and contemptuous enemies, to "refinement" and "culture", qualities which will surely enough attend in due measure upon all healthy activity; my hope is that nothing short of the most vigorous performance of all those functions in relation to study and professional training of all kinds, elsewhere discharged by universities, will be admitted as worthy of the venerable "mother of sciences", who is surely capable of doing more than teaching manners.

The general question as to the advisability of separating the preliminary, introductory, and technical parts of a medical education is raised in Dr. Ord's letter. I do not think that it is possible to bring forward a single argument in favour of their being separated as to place, though a proper succession in these studies as to time is necessary. On the other hand, there are the strongest reasons for keeping them united in place. The mere talk of separating them encourages an attitude towards these studies which is, I venture to submit, entirely erroneous and injurious. Dr. Ord says, "It is with medicine as with seamanship—in both, science and practice are appropriately taught in different places". The analogy, to hold good, requires that there should be the same absence of sick persons on whom to practise medicine in the neighbourhood of the school of medical science, as there is absence of sea from the neighbourhood of the school of naval science. So far as Oxford is concerned this is not the case. The Radcliffe Infirmary (and here I regret to have to contradict Dr. Chambers, whose remarks must be understood as referring to one set of beds only, viz., Dr. Acland's) is notoriously (as its annual reports exhibit) one of the best fields for clinical instruction in the kingdom, not excluding the London hospitals. It has 200 beds, into which are received a considerable variety of interesting surgical cases, as well as a large number of fever cases, besides the usual cases of chronic disease. But my objection to Dr. Ord's view goes beyond the objection to his analogy. I cannot admit that there is any such sharp line as he would draw between "science" and "hospital work". I would quote the opinion expressed by Professor Billroth, in support of my contention that there is *but one method* (call it science or call it practice) of investigating nature. The very same faculties of the mind, and even the same technical processes, are made use of in observation and reasoning at the sick-bed and in the chemical laboratory. It is very desirable in order that the medical student may have the full advantage of the scientific method, that he be not encouraged to divorce his more special from his more general studies under the names of "practice" and "science" respectively, and that the association of the two in one university town be maintained so that the students and the teachers of all branches of science may mingle and give aid to one another. It is, moreover, desirable that the more special and professional part of a medical education, the part which Dr. Ord calls "practice" be given in the same place as the more general parts of medical education, because in this way there is the surest guarantee that these more general parts are *efficiently* carried through, and in such a way as the due training of a medical man demands. The local proximity of the teaching of the special studies need in no wise injure such a thing as a biological school, unless the two institutions are brought into competi-

tion by a poverty of pecuniary resources. This, of course, need never occur in Oxford, whilst the juxtaposition alluded to is calculated to give a seriousness, a professional dignity, to the preliminary and general studies, resulting in a thoroughness and purpose which they otherwise must lack.

The point at which a line between science and practice may with justice be drawn is when the medical student has completed his curriculum, and actually, as the common use of language puts it, "enters into practice". This might, perhaps, be regarded as the equivalent of the scientifically taught sailor's putting to sea, though I do not think the analogy a serviceable one.

Let me, in conclusion, say that there is an increasing number of fellows of colleges resident in Oxford, and of other graduates resident in the university, who have very serious cause to regret the fact that it is not possible to pursue their medical studies in the Radcliffe Infirmary and to proceed to graduate in medicine. These persons, and the graduates who form the resident portion of the governing bodies of the Colleges, are amongst those who are best able to judge of one aspect of the question whether it is desirable that Oxford should have a medical faculty. In some respects they may give a more impartial verdict than can be expected of those who have taken the Oxford degree in medicine and have ceased to have an intimate connection with the place.—I am, Sir, your obedient servant,

E. RAY LANKESTER, M.A., F.R.S.,  
Fellow of Exeter College, Oxford.

### THE REPRESSION OF QUACKS.

SIR,—Herewith you will find a draft of a Bill\* now before Parliament for the Amendment of the Medical Act, 1858. It is wished merely to have the means of carrying out effectively the spirit of the Act, as intended by the Legislature when the Act was passed, whilst, at the same time, a provision is desired to be made for the recognition and registration of respectable foreign diplomats.

The Act, as expressed in its preamble, was intended to "enable persons requiring medical aid to distinguish qualified from unqualified practitioners", but, in consequence of the looseness of the wording of its penal clause, this object has been frustrated, and the public, especially the poorer classes, are still exposed to the danger of falling into the hands of ignorant medical impostors who are practising in swarms under the cover of high-sounding and attractive titles pretended to be conferred by purchased fictitious and disreputable foreign qualifications.†

To show the conflicting constructions put upon the penal clause of the Act by some magistrates when dismissing, and others when convicting in the same class of offences, and so to illustrate its nugatory purposes, a few cases have been selected for your information, and will be found on one of the following pages.—I am, sir, your obedient servant,

R. H. S. CARPENTER, Honorary Secretary.  
Medical Alliance Association,  
130, Stockwell Road, S.W., February 1878.

DRAFT OF A BILL PROPOSED BY THE MEDICAL ALLIANCE ASSOCIATION FOR THE AMENDMENT OF THE MEDICAL ACT, 1858.

*An Act to Amend an Act passed in the twenty-first and twenty-second years of the reign of Her Majesty, "to regulate the qualifications of Practitioners in Medicine and Surgery", and commonly known as the Medical Act, 1858.*

WHEREAS an Act was passed in the twenty-first and twenty-second years of the reign of Her Majesty "to regulate the qualifications of Practitioners in Medicine and Surgery"; and whereas it is expedient to amend the said Act :

\* This Bill was introduced into the House of Commons by Dr. Lush, Sir Trevor Lawrence, Mr. Ritchie, and Mr. Samuda, and read a first time on the 15th January last.

† The Medical Act (1858) unintentionally permits persons who have received no medical education, to purchase "bogus" diplomas, to assume foreign medical titles, to attach those titles to their residences, and to indecent pamphlets, which they may distribute by thousands through the post and by hand. Illustrative case: A man calling himself "Dr. Harrison, F.S.A., Member of the Royal College of Physicians and Surgeons, N.Y., U.S.A.; de la Société de Médecine de Rouen; National Academy of Sciences; Fellow Institute of France, of England, etc.", was charged at the Clerkenwell Police Court, in February last, under Lord Campbell's Act, with distributing through the post, and otherwise, indecent pamphlets. Five bags full of these papers had been seized by the police, and in one bag were one thousand six hundred and seventy pamphlets, in envelopes, already directed and ready for posting. Notwithstanding that the contents of the five bags were ordered by the magistrate to be destroyed, this man cannot be convicted under the Medical Act, for the reason that he is not assuming medical titles recognised by that Act. The consequence is that he is left, as are all like him, to practise on the public under cover of his long string of spurious medical qualifications, without having any cause to fear a prosecution under the Medical Act.

Be it therefore enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons in this present Parliament assembled, and by the authority of the same, as follows.

1. Section 40\* of the said recited Act is hereby repealed; and in lieu thereof it is enacted: Any person who, for the purpose of gain, shall take or use the name or title of physician, doctor of medicine, licentiate in medicine, licentiate in surgery, bachelor of medicine, surgeon, general practitioner, apothecary, or any other medical or surgical name, title, or description purporting to authorise the practice of medicine or surgery, unless such person holds a qualification or qualifications entitling him to take or use such name, title, or description, and such qualification or qualifications be also registered under the said recited Act, shall, upon summary conviction for either or any such offence, pay a sum of twenty pounds.

Any person who, for the purpose of procuring the registration of the cause of death of any deceased person, shall make, fill up, or sign, any medical certificate of the cause of such death, unless he personally attended such deceased person during his or her last illness, and holds a qualification in medicine or surgery duly registered under the said recited Act, shall, upon summary conviction for either or any such offence, pay a sum of twenty pounds.

If any person shows that he is not a British subject and not ordinarily resident in the United Kingdom, and holds a medical diploma, degree, or title from some university, college, or body in any British possession or foreign country entitled to grant the same, such person shall not be liable to any penalty under this Section.

2. To Section 42† of the said recited Act, the following words shall be added, viz., anything to the contrary in any Act passed before the passing of this Act notwithstanding.

3. To Schedule A of the said recited Act, this Section shall be added: When the General Medical Council are satisfied that any medical diploma, degree, or title granted by any university, college, or body in any British possession or in any foreign country is granted in respect of a degree of knowledge in both medicine and surgery equal to that required for obtaining a licence in both medicine and surgery under the said recited Act, they may from time to time, if they think fit so to do, place such diploma, degree, or title upon the *Medical Register*, and if at any time any such medical diploma, degree, or title ceases to be granted in respect of such degree of knowledge as aforesaid they may remove the same from such *Register*.

4. This Act to be read with, and form part of, the same recited Act.

5. This Act may be recited for all purposes as the Medical Acts Amendment Act, 1878.

#### CONTRASTING CASES.

**Convictions.**—A few years since, a gentleman in good social position, named T—, and holding one of the best medical qualifications—that of the Society of Apothecaries—was fined £20 in the Lambeth Police-Court for using the title of "Surgeon", instead of "Apothecary".—In the Clerkenwell Police-Court, a man named Kerr, who held an American diploma, was fined £5 for falsely pretending to be a Doctor of Medicine, the magistrate (Mr. Cooke) saying at the time that he convicted him that "no diploma from abroad would give the defendant the right to use the title of Doctor".—In the Hammersmith Police-Court, a man named Swallow, who held an American diploma, was fined £5 for using the title of Doctor of Medicine.—In the Clerkenwell Police-Court, a man named Kahn, who held an American diploma, was convicted in a penalty of £5 for falsely pretending to be a Doctor of Medicine.—At Bolton, a man named Foulds, who holds two American qualifications, was convicted by the magistrates for taking the title of "Doctor".

**Dismissals.**—In the Marlborough Police-Court, a charge against a man named Hamilton of falsely pretending to be a Doctor of Medicine, under cover of a sham American diploma, was dismissed, the magistrate (Mr. Mansfield) observing at the time that "a person might call himself a Doctor the same as a Captain, if he pleased".—In the Marl-

borough Police-Court, a man named Hamilton was charged with falsely pretending to be a Doctor of Medicine, upon the faith of his holding a diploma from an American college, there being no such college. Mr. Knox dismissed the charge, saying at the time that, "unless a title recognised by the Medical Act was assumed, no offence would be committed under the Act".—In the Thames Police-Court, a charge against a man named Dixon (who held a foreign qualification in dental surgery) for falsely pretending to be a Doctor of Medicine, was dismissed, apparently because he had not described himself to be registered.—A charge against a man named Le Page (who held no medical qualifications whatever), of falsely pretending to be a Surgeon and Physician, and signing a certificate as such, was dismissed by the Durham magistrates, who refused to accede to the request of the solicitor for the prosecution to grant a case for a superior court.—In Liverpool, a charge brought against a Mr. Hamilton, for having signed a death-certificate under the title of "Botanic Surgeon", and otherwise using the title of "Surgeon", was dismissed by the magistrate. The defendant proved that he held an American diploma (?) in "Botanic Surgery".

## MILITARY AND NAVAL MEDICAL SERVICES.

### NEW REGULATIONS FOR THE HOSPITAL CORPS OF THE ARMY.

NEW regulations, embodying very important changes in the constitution, and in the functions of some of the officers of, the Army Hospital Corps, have just been issued by the War Office. Hitherto the captains and lieutenants of orderlies have been alone invested with command, and held responsible for the maintenance of discipline in the corps; these duties and responsibilities have now, by the present regulations, been formally delegated in the first instance to the medical officers, under whose direction and orders the officers of orderlies will act in all capacities in future. The medical officers are placed, by these fresh rules, in an entirely new position, and it is one which will demand the exercise of special tact, diligence, and discretion, for the trusts and responsibilities imposed on them by it to be satisfactorily discharged. We are not, however, among those who have a dread that medical officers, by being invested with command, will estimate unduly the military functions, and at the same time underrate and neglect their strictly professional duties; we rather indulge the hope that the increased authority conferred on them will be merely regarded as a means of enabling them to apply their professional knowledge and directions with more practical effect and in a more systematic manner, and in the best interests of their patients.

The regulation just issued for the Army Hospital Corps, entering as they necessarily do into many details of duty, form a rather lengthy pamphlet of nearly fifty pages, but a brief analysis of them will sufficiently explain their general scope and bearing. The duties for which the corps has been organised, the mode of recruiting the corps, the manner in which disciplinary control is to be exercised in it, and its interior economy to be administered, are laid down in the first section. The corps has been organised for duties in connection with the hospital service of the army, and is an integral part of the Army Medical Department. The administrative charge of the corps is vested in the Director-General, and the principal medical officer of each military district, subject to the general officer commanding it, will represent the Director-General and exercise supreme authority in all matters of discipline affecting the corps in his district. The medical officer in charge of each general station and field hospital will have disciplinary control over the officers, non-commissioned officers, and privates of the Army Hospital Corps attached to the hospital. The head-quarters of the corps are at the office of the Director-General of the Army Medical Department, where all the records of the corps are to be preserved. In keeping up these records, the Director-General is to be assisted by a functionary entitled the "staff-officer" of the corps. The dépôt of the corps is placed at Aldershot, under the immediate command of a medical officer appointed by the Director-General. This is a very important establishment. The medical officer commanding has under his orders an adjutant, quarter-master, and officer of orderlies in charge of the equipment stores. The instructor and assistant-instructors of the corps also form part of the dépôt. All recruits joining the corps are, in the first instance, to be sent to this dépôt and put through a course of recruit drill. As soon as they are dismissed from this drill they are to be placed at the disposal of the medical instructor, for the purpose of going through a course of professional instruction, and of stretcher and bearer-column drill. They remain at this dépôt during the whole course of training, and it is specially laid down in the regulations that they are not to be removed from the dépôt for any purpose

\* Section 40, which it is proposed to repeal, is thus worded: "Any person who shall wilfully and falsely pretend to be, or take or use the name or title of a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, surgeon, general practitioner, or apothecary, or any name, title, addition or description implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or licentiate in medicine or surgery, or a practitioner in medicine, or an apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds."

† Section 2 merely carries out the intention of the 42nd section of the Medical Act (1856), which says: "Any sum or sums of money arising from conviction and recovery of penalties as aforesaid, shall be paid to the treasurer of the Medical Council." The penalties hitherto recovered in the metropolitan police district, under this clause, have been claimed and retained by the metropolitan police receiver under the provisions of an old Act of Parliament.

without the express sanction of the Director-General. These regulations ought to ensure that every hospital orderly in future shall be thoroughly prepared for the efficient discharge of hospital duties, whether he be employed in the stationary hospitals of peace-time, or in those adapted to meet the wants of active service in the field.

The sections of the regulations which follow define the function and responsibilities of the district officers, of orderlies, of those attached to station-hospitals for duty under the medical officers in charge, and, lastly, of the non-commissioned officers and privates of the corps. One section is devoted to an explanation of the qualifications required in those non-commissioned officers who desire to undergo a course of training and instruction to fit them for being employed as compounders of medicines, and of the plan of proceedings by which their knowledge of the subjects in which they are required to be proficient is to be tested. A list of the various forms of returns and books which are required to be kept up in connection with the corps, and which appear to be sufficiently numerous, is appended to the regulations. The sections just referred to enter into many particulars which it is, doubtless, essential to define with precision in a code of regulations; and which, consequently, occupy a considerable amount of space in description. It would be out of place to notice them further in these pages. Sufficient has been quoted to show the nature of the new regulations, and to indicate the great change which they involve as regards the status and powers of the medical officers of the army. We congratulate the Director-General in having achieved such an important elevation of the officers of his department in army *prestige*; and we hopefully trust that the medical officers will show their appreciation of it by hereafter making manifest that the administration of the hospitals, and the discharge of all their other professional duties—so far from suffering by the change, as some would like to see—have, on the contrary, improved in proportion to the increased power in the control and direction of their professional concerns with which they have now been vested.

## · OBITUARY.

### FLEETWOOD CHURCHILL, M.D.

IT is with no ordinary sorrow we chronicle the death of this eminent obstetrician, briefly announced in the JOURNAL of February 2nd. The sad event took place on the 31st ult. at Ardrea Rectory, County Tyrone (the residence of his son-in-law, the Rev. Dr. Mead), where Dr. Churchill lived since his retirement from practice in June 1875.

Except that of Simpson, there is, perhaps, no name so widely known to the obstetric world as that of Fleetwood Churchill. His writings on every branch of the third estate of medicine—viz., on the Diseases of Women, on the Diseases of Children, and on Pure Midwifery—had a world-wide fame. Although an Englishman by birth, yet Ireland was the country of his adoption and of his warmest affections.

In 1831, Dr. Churchill obtained his degree of M.D. at Edinburgh, and, in the following year, he became a Licentiate of the King and Queen's College of Physicians of Ireland, and took out the Licence in Midwifery of the same College. Having contracted by marriage a close tie to Dublin, he settled down to practise there, and from the very first devoted himself to the obstetric branch of medicine. In furtherance of this object, he, in conjunction with the late Dr. Speedy, started a small lying-in hospital on Arran Quay—"The Western Lying-in Hospital"—where, for some years, they instructed a class of students in midwifery. Interesting clinical reports of the practice of this hospital were published by Churchill in the pages of the *Dublin Medical Journal* for the years 1838-9-43.

In 1848, the honorary degree of M.D. was conferred upon him by the University of Dublin. About the same time, he was elected an Honorary Fellow of the King and Queen's College of Physicians; and in 1851, a Fellow of the same College. In 1856, he succeeded Dr. Montgomery as King's Professor of Midwifery in the School of Physic. This professorship he held till 1864, when his increasing practice compelled him to resign it, whereupon Dr. Sinclair, the present professor, was appointed in his stead.

Dr. Churchill was twice elected President of the Dublin Obstetrical Society; namely, in 1856 and again in 1864; and at the time of his death was an Honorary President of the Society. During the years 1867-8, he filled the Presidential Chair of the College of Physicians. The important duties of this position he discharged with ability, courtesy, and exemplary diligence. His *obstetric* predecessors in this chair were Beatty, Evory Kennedy, Montgomery, and Collins.

At the annual meeting of the British Medical Association, in 1874, at Norwich, he was chosen President of the Obstetric Section. A severe illness prevented his attending; but the address he had pre-

pared, on the Hygiene of Lying-in Hospitals, was read by the Vice-President and excited much interest, as the questions to which it related were then being keenly discussed both within and without the profession. He was also an ex-President of the Dublin Pathological Society.

To his intimate friends, Churchill always expressed his determination to give up professional work whenever he found his bodily health unequal to the faithful and honest discharge of the duties required of him. True to this resolution, he relinquished the responsibilities and cares of practice in June 1875, left Dublin, and settled with his married daughter in the County Tyrone. It required no ordinary effort to make up his mind to this step, as he had many intimate ties and warm friendships in Dublin. He frequently expressed to the writer of this sketch that it was "a terrible wrench"; but he felt it was the right thing to do; and, having once made up his mind on this point, all conflict was over and he entered on the new path with resignation and cheerfulness. He never revisited Dublin.

Churchill was a great lover of books, and had made, in the course of his life, a very large and valuable collection of works, ancient and modern, upon every branch of Obstetrics. His writings abundantly testify to what good account he turned his study of these works. With true public spirit, Churchill presented the above rare collection of books to the College of Physicians on his retirement from practice; and the College, in return, presented him with an address couched in the most flattering terms; and also directed his portrait to be painted and placed in the grand hall of the College. This portrait, executed by Mr. Jones, President of the Royal Hibernian Academy, is a speaking likeness, and occupies an honourable position among the marble and canvas effigies of Graves, Stokes, Marsh, and Corrigan, and of Sir Patrick Dun, Beatty, Mayne, and Percival.

The Obstetrical Society was also forward to do him honour, and conveyed the expression of their deep regret at his departure, and of their respect and esteem towards himself, in a highly complimentary address. He was one of the few surviving original members of this society, and for thirty-seven years had been a regular attendant at its meetings, always taking an active but temperate part in the discussions. Many of his numerous essays and memoirs made their first appearance in public at the reunions of this Society.

His voluminous works on the Diseases of Women, Midwifery, and the Diseases of Children are so long and so well known to the obstetricians of all countries, that we need do no more than mention them. For over twenty years, they were the established text-books on these subjects. They are all characterised by great erudition and research, and by full acknowledgment of every author from whom he borrowed a quotation or an opinion. It deserves here to be stated that, though largely availing himself of the writings of others, he was always scrupulously particular in acknowledging his obligations. The charge of plagiarism was once made against him, but it signally failed and recoiled upon the head of its author.

His celebrated *Treatise on Midwifery* possessed, in addition, this feature: that he used the published statistics of all authors of any repute, in the elucidation of very many practical questions. These results he carefully tabulated much in the same manner that Collins had previously done with regard to his hospital cases. The amount of work thus compressed into a small compass by Churchill was simply enormous; but he was a man of extraordinary industry, and never was a moment idle. He was, moreover, a rapid writer, and so strict an economist of time, that he got through a great amount of reading in his carriage, when driving from place to place, and in this way chiefly he kept *au courant* with the literature of the day.

A great deal of the material of which his works are made up originally appeared, in a detached form, in the pages of the *Dublin Medical and Surgical Journal*, especially in the first and second series of this long established periodical. The number of his communications to the Obstetrical Society was also very considerable, scarcely a session passing without one or two. Even after his departure from Dublin, he forwarded two papers to the Society, which were read by his son Dr. F. Churchill. The latter of these papers, *On Uterine Polygus*, was read at the meeting of May 12th, 1877.

The Council of the *Old Sydenham Society* appointed Churchill, in the year 1848, to edit certain monographs on Diseases of Women. This volume appeared in 1849. The greater part of it is occupied by tracts on puerperal fever, to which the editor prefixed an historical sketch of the epidemics of that malady. "I have collected," he says, "with some labour, all the information within my reach, and I trust that the summary will be found tolerably complete." This sketch occupies forty-two pages, and is a very valuable contribution to the literature of the subject of which it treats, up to the time when it was written.

For some years before his retirement, Dr. Churchill was largely en-

gaged in practice, and enjoyed alike the confidence of the public and of his professional brethren. He had a wide circle of attached friends both within and without the profession; for his sterling rectitude of character, coupled with his kindness and urbanity of manner, won the respect and esteem of all who knew him. Though a man of deep earnest religious feeling, he was singularly free from cant or sectarianism; and preferred that his religion should be an operative principle, influencing and controlling his words, acts, and conduct, rather than a mere matter of talk and ostentation. He has often said to the writer of this sketch that "he would not give a fig for a man's religious principle, if it did not make him strive to be a better doctor, lawyer, or soldier, as the case might be".

As might be expected in a man actuated by such principles, Churchill's professional conduct and bearing, especially towards his brother practitioners, were consonant with the strictest rules of medical ethics. In this sense, he was indeed a man:

"Totus, teres, atque rotundus."

His fame will be perpetuated by his writings, and his remembrance will be fondly cherished in the hearts of those who knew him.

For many years, he had a very extensive midwifery practice, which he gave up some time previously to his retirement from Dublin. He submitted a long and detailed account of this series of cases to the Obstetrical Society, which was subsequently published in the *Dublin Medical Journal* for June 1872. This report extends over thirty-nine years, and exhibits the results of 2,547 cases of labour, exclusive of abortion and premature cases. As a record of the results of practice among the better classes of society in a great city, this report is most valuable.

Churchill's whole career furnishes a bright and encouraging example of success attained solely by industry, application, and honourable conduct. The influence such a man must exert in upholding the tone and standard of professional feeling amongst his contemporaries can hardly be overestimated.

For some years back, Dr. Churchill suffered from chronic rheumatic arthritis of the hip-joints; and also was known to have a weak heart, so that the slightest fatigue brought on faintness or was followed by prostration. The immediate cause of his death, however, seems to have been an acute attack of bronchopneumonia, under which the vital powers rapidly broken down. He died in the last month of his seventieth year.

In fine, to quote from the Address of the Dublin Obstetrical Society, his was a "lengthened career not less distinguished for the conscientious discharge of every professional obligation than for the successful cultivation of all the branches of obstetric science and for the promotion of every useful and philanthropic work that came within his reach."

## MEDICO-PARLIAMENTARY.

*HOUSE OF COMMONS.—Monday, February 11th, 1878.*

*The Medical Students and the War.*—Dr. WARD defended the course adopted by the deputation of medical students of London to the Home Secretary, which had been warmly assailed by Mr. Hubbard. That right honourable gentleman had said that the course they had pursued was most deplorable, and that they were evidently looking forward to an opportunity of exercising their profession. In his opinion, that was a most unfair charge to bring against a number of young men who, in their collective capacity, had thought it right in this grave crisis to express their confidence in Her Majesty's Government.—Mr. HUBBARD explained that the only fault he had found with the deputation of medical students was, that they had passed a resolution, amid vociferous cheers, in favour of war with Russia. He approved their passing a vote of confidence in Her Majesty's Government, inasmuch as he had himself voted in their favour.

*Tuesday, February 12th.*

*Sale of Food and Drugs.*—Mr. ANDERSON asked the President of the Local Government Board whether his attention had been called to a recent decision of the High Court of Justiciary, Scotland, concerning the Sale of Food and Drugs Act, 1875, by which five judges had decided that no offence could be proved on evidence taken from any article specially bought for analysis, the buyer in such case not having been prejudiced in the purpose for which he bought it; and, further, that two of the judges—Lords Moncreiff and Young—expressed the opinion that the sixth section did not prevent tampering with an article to the deterioration of its quality, if without the addition of extraneous matter; and whether he purposed taking any steps to prevent the Act in question becoming a dead letter.—Mr. SCLATER-BODDIE: My attention has been called to the decision of the High Court of Justiciary in

Scotland to which the honourable gentleman refers, and I regret that I have not had an opportunity of conferring with the Lord-Advocate on the subject. It seems that, previous to the Scottish case alluded to, no question had been raised in England as to the validity of a prosecution under the Sale of Food and Drugs Act by a person who purchases only with a view to analysis, and in the cases which have occurred since the magistrates have decided against the objection when raised. I concur in that view, which, be it observed, is also the view of some of the Scottish judges; and I cannot believe that the High Court of Justice, if appealed to, will come to any other decision. I am, therefore, not prepared, as at present advised, to introduce an amending Bill, though, if my anticipations were disappointed, such a step might be necessary.

## MEDICAL NEWS.

### MEDICAL VACANCIES.

The following vacancies are announced:—

- DOWNPATRICK UNION**—Medical Officer of Strangford Dispensary District. Salary, £100 a year as Medical Officer, and £15 as Sanitary Officer, with the usual Registration and Vaccination Fees. Election to take place on the 21st instant.
- GENERAL INFIRMARY, Hertford**—Medical Resident and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before March 6th.
- GENERAL INFIRMARY, Northampton**—Surgeon. Applications to be made on or before the 27th instant.
- GORT UNION**—Medical Officer of Ardahan Dispensary District. Salary, £140 a year as Medical Officer, and £10 as Sanitary Officer, with Registration and Vaccination Fees. Election on March 14th.
- IPSWICH BOROUGH LUNATIC ASYLUM**—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance.
- KILLALA UNION**—Medical Officer of Killala Dispensary District. Salary, £60 yearly, and £20 as Sanitary Officer. Applications to the 2nd prox.
- LINCOLN LUNATIC HOSPITAL**—Resident Medical Superintendent. Salary, £150 per annum, with board, lodging, and washing. Applications to be made on or before the 16th instant.
- LIVERPOOL ROYAL SOUTHERN HOSPITAL**—Two Honorary Surgeons. Election in February. For particulars, apply to Honorary Treasurer.
- NARBERTH UNION**—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.
- NORTHAMPTON GENERAL INFIRMARY**—Physician. Applications to be made on or before the 20th instant.
- WESTMINSTER HOSPITAL**—Aural Surgeon and Assistant Surgeon. Applications to be made on or before the 26th instant.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

**TOMKINS, Henry, M.D.**, appointed Senior House-Surgeon to the Manchester Royal Infirmary.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

#### BIRTHS.

- \***GRIFFITH**.—On February 9th, at Portmadoc, North Wales, the wife of Samuel Griffith, M.D., of a daughter.
- THOMSON**.—On February 6th, at Algiers, the wife of W. Thomson, M.D., of a son.

#### MARRIAGES.

- APPLEYARD**—DEACON.—On the 9th instant, at Christ Church, Banbury, John Appleyard, F.R.C.S., M.B., to Matilda, daughter of the late Grosvenor Deacon.—No cards.
- HENNING**—STRICKLAND.—On the 12th instant, at St. James, Norland (W), \*Wm. Douglas Henning, M.R.C.S., of Notting Hill Terrace, Senior Assistant Surgeon to the Central London Throat and Ear Hospital, to Harriet Isabella, daughter of Major Strickland, and granddaughter and adopted child of Mrs. Major Dickson, of Notting Hill.
- JONES**—ROBERTS.—On February 2nd, by License, at Saint Chad's Church, Shrewsbury, by the Rev. Ed. Lloyd Edwards, M.A., John Jones, Esq., M.R.C.S. Eng., L.S.A., to Sarah, only daughter of John Roberts, Esq., of Bryn End, Ruabon.

#### DEATH.

- TIBBITS**.—On the 10th instant, at 11, Eldon Place, Bradford, Yorkshire, Charlotte Bankes, the wife of Edward T. Tibbits, M.D. Lond., in her 39th year.

**DONATION.**—The Misses Brooke have given £100 to the Rathdown Hospital, Monkstown.

**DR. CORNELIUS B. FOX**, Medical Officer of Health of East, Central, and South Essex, has been elected a Fellow of the Chemical Society.

A LIFE-SIZED portrait of the late Dr. Parkes, F.R.S., intended for the Refectory at Netley, has just been completed by Messrs. Barraud and Jerrard, and is on view up to the 16th instant, at 96, Gloucester Place, Portman Square.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Mr. Balmanno Squire, "Two Cases of Flat Vascular Nevus successfully treated by repeated Linear Scarifications"; Mr. William Adams will exhibit Improved Instruments for the Treatment of Broken Nose; and Mr. Spencer Watson Improved Instruments for the Treatment of Distortion of the Nose; Mr. Wordsworth, "On the Treatment of Squinting without Operation".

**TUESDAY.**—Pathological Society of London, 8.30 P.M. Mr. Knowsley Thornton (for Mr. Taylor of Guildford): Tumours of both Ovaries. Mr. Thornton: Cysts from the Peritoneum. Mr. John Wood: Cystic Disease of the Thyroid. Dr. Pencock: Malformation of the Heart. Dr. Samuel West: Thrombosis of the Vena Cava, with Secondary Thrombosis of the Portal Vein. Dr. Wickham Legg: 1. Aneurysm of the Right Auricle; 2. Melanotic Liver. Dr. Goodhart: 1. Dilatation of the Aorta from old Spinal Disease; 2. A Case of general Arterial Disease. Mr. Charles Coles: Worms in the Heart, Liver, and Larynx of a Dog. Mr. B. Squire: Drawings—1. A rare form of Psoriasis; 2. A Case of Nevus complicated with Molluscum. Mr. Sangster: Case of Hypertrophied Lupus. Dr. Ord: 1. Renal Calculus containing Indigo; 2. Renal Calculus of mixed Carbonate and Phosphate; 3. Spontaneous Disintegration of Calculi; and other specimens.

**THURSDAY.**—Harveian Society of London, 8 P.M. Dr. G. de G. Griffith, "A Case of Hydrannios"; 8.30 P.M., Mr. Knowsley Thornton, "On Unsuccessful Ovariectomy: with Cases".

**FRIDAY.**—Quekett Microscopical Club (University College, Gower Street), 8 P.M. Ordinary Meeting.

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

The letters of Mr. W. J. Marsh, Dr. Ogle, Dr. Donkin, Dr. Campbell, and many others, are unavoidably postponed for want of space.

## AN APPEAL.

SIR,—On behalf of the family of a distressed medical man, I have to thank those who have so kindly responded to my appeal. Lay subscriptions I have acknowledged elsewhere. At the same time, I shall feel greatly obliged for further assistance, which is needed and deserved.—Yours faithfully,  
JOHN J. EBERLE.

G. Shann, M.D.	..	..	..	£2	2	0
C. Coates, M.D.	..	..	..	..	2	0
A. Clark, M.D.	..	..	..	..	2	0
T. C. Allbutt, M.D.	..	..	..	..	1	0

J. Baker, M.D.	..	..	..	..	0	10

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a Post Office.

## THE POPULATION QUESTION.

SIR,—With reference to Mr. Allbutt's pertinent remarks in your impression of February 2nd, 1878, allow me to say his penultimate sentence would seem to do what it is impossible he can have intended—viz., to qualify, repudiate, or negative all he has urged with regard to the principles under discussion. To urge, "Surely there is sufficient poverty and evil in the world without bringing in more to share it than can be provided for," implies either begging the question at issue—a direct imputation that the world is at present very badly managed—or that all persons should take it upon themselves to say how much poverty and evil will exist in any part of the world in the future, or limit the productiveness of any race because inadequate means of feeding, clothing, or employing them may be adopted in that part of time sometimes called unborn eternity. As a rule, the result usually has been, limit the increase of population without adequate cause, and the reaction causes deterioration or annihilation.—Yours, etc.,  
J. A. P. BAIN.

Aberdeen, February 4th, 1878.

## BIRMINGHAM PROVIDENT DISPENSARY.

SIR,—My attention has been directed to some remarks in your last issue on the proposed dispensaries in Birmingham, and on my conduct as one of the honorary secretaries of these institutions. Were it not that the remarks to which I refer are utterly without foundation in fact, I should not venture to ask you to give me space to contradict them, for of course the dispensary scheme and its promoters are open to fair criticism. You allege that "the lay committee on provident dispensaries went on with their work without taking counsel with the medical profession, and they published about a fortnight ago their scheme of rules for the Birmingham dispensaries." Neither of these statements has the merit of being true. Our committee did not consult the medical societies for several reasons—among others, because those societies do not include all the medical practitioners likely to be affected by our scheme, and they do include many specialists and rural surgeons not directly concerned in it. But it ought not to be forgotten that the town's meeting called by the mayor to establish provident dispensaries was open to the medical profession as to any other class of the community; and yet, with the exception of a few consulting surgeons who allowed their names to go on the committee, the medical men were not present to show any interest in the movement. They stood entirely aloof till they thought our committee was formulating a scheme that would touch their professional interests, though the committee had no desire to do anything hurtful to the status of a class of men who are deservedly respected, and who are everywhere overworked and badly remunerated for what they do. The committee has from the first recognised the necessity of sooner or later consulting the profession—at any rate, that portion of it directly affected by their scheme—but they have been at a loss to know how this might best be done. With regard to the publication of our scheme, I can only say that it has not been published by us. Up to the present time, a complete scheme does not even exist. The draft of one was issued to the medical charities, and to the officers of large industrial societies, but it was never intended to be published as a finished scheme. We owe the publication of our rules in their present imperfect state to what I cannot but regard as a questionable trick. The President of the Branch of the British Medical Association, without consulting our committee, went to our printers and got four hundred copies struck off from our type, which is still standing for further corrections. There was really no occasion for an act of this kind, since he could have had copies from us by simply asking for them.

As to our scale of remuneration for professional services, that was determined on the evidence of labour representatives on our committee, who are also officers of large provident and sick societies; and if the statements of the honorary secretary of the Birmingham General Provident and Benevolent Institution, which appear in the *Daily Post* of to-day, be correct, our scale of remuneration will bear favourable comparison with that of existing dispensaries. The following is an extract from his letter.

"I beg to point out that this is not a new idea. It has not only been long felt, but, by the exertions of the late Mr. Sanders, M.R.C.S., it was put into practice, and ever since 1833 has been carried out by the Birmingham General Provident and Benevolent Institution, the chief office being No. 49, Ann Street, and it numbers now over five thousand members. In this self-supporting, not charitable, institution, any party, male or female, can provide for themselves medical attendance and medicine in case of illness by the payment of 4d. per month or 4s. per year, and for their children at a lower rate. For the payment of 4d. per month, or 4s. a year, the members have the right to call in the attendance of any one on a list of twenty-four surgeons (and as a list I may say it is second to none), and residing in all parts of the town; thus giving the members the privilege, on changing their residence, to select a surgeon in their own immediate locality. Another privilege, which I believe no other society can offer, is that a member, on changing his residence, can pay his contributions without having far to go, the society having about twenty offices scattered all about the town."

The other statement to which I would refer is altogether personal, and affects myself. It is as follows. "The Town Hall Committee decided that the first dispensary should be established at Hockley, and that it should begin with a staff of four surgeons: the honorary secretary of the committee, an Unitarian minister, thereupon visited three members of the Birmingham Branch of the Association, and proposed that they should become surgeons to the projected dispensary." So early the whole of this paragraph is pure romance. The committee did propose to open an experimental dispensary in Hockley after consultation with all the medical men in that district, but did not resolve that they would begin with a staff of four surgeons; and the honorary secretary was not empowered to make proposals to any surgeon, and he never made any. The committee has not even considered the immediate appointment of surgeons, and has not, therefore, passed any resolution on the subject, and my interview with four medical men was entirely unofficial. These gentlemen could not have understood that it was in my power to treat with them. My object in consulting them was simply to know for myself the nature and extent of professional objections to our scheme, and to dispose of the gentlemen, as far as I was able, to give our movement fair and generous consideration. They were most distinctly told that the laws were open to amendment, and were by no means finally

settled. But it surely must be obvious to every one, that if our committee wanted a medical staff for a branch dispensary, it would not send one of its secretaries to make proposals to three out of the score surgeons in the district, and eligible for such work.

Before closing this lengthy explanation, permit me to say that the Dispensary Committee has not slighted the profession, and has no interest hostile to it; and if a joint committee be formed, consisting of representatives from the medical societies and our committee, they will soon make short work of those disputed points, which relate chiefly to matters of detail, and are of no particular importance.—I am, sir, yours very respectfully, J. CUCKSON, Hon. Sec. Birmingham 36, Northampton Street, Feb. 5th, 1878. Provident Dispensary.

\* The first portion of the paragraph which Mr. Cuckson says is not true—viz., "the lay committee went on with their work without taking counsel with the medical profession", was perfectly true up to the middle of last week. We are glad that his committee has at last seen its error, and is now trying to rectify it. We accept Mr. Cuckson's statement that his draft laws have never been, in the technical sense, "published"; but he himself shows that they were, by the act of his committee, in the hands of many persons, both lay and medical, and if not "published", were at all events very public, so that copies might have been had from them "by simply asking for them". It is quite true that Mr. Cuckson called on several members of the Branch, who believed that he did so with the view of inducing them to become surgeons to one of the new dispensaries. We of course accept his statement that these gentlemen were mistaken; but so natural a mistake cannot be properly designated "pure romance". We learn from his letter that there already exists in Birmingham a thriving provident dispensary. Why does not Mr. Cuckson endeavour to co-operate with this institution? It would *prima facie* be better to extend its operations, enlarge its sphere, and, if needful, amend its organisation, than to establish a rival. Mr. Cuckson's committee have already responded to our appeal to consult the Branch; perhaps they will now take our last suggestion into their favourable consideration.—Ed. P. M. J.

#### JUDICIAL POST MORTEM EXAMINATIONS IN SCOTLAND.

SIR,—I am sorry that you should have so far misunderstood and misrepresented the complaint made by me in the correspondence on which you commented in your JOURNAL of Saturday last. The principal ground of my complaint was, not "that the *post mortem* was handed to another", but that the Fiscal caused an unnecessary examination to be made in a way very offensive to the feelings of the family of the deceased; and that, too, without taking the trouble to follow what he himself says is his usual course—namely, to inquire of the medical man called by the friends whether or not there was "a notable absence of the characteristics of death from natural causes". He has laid down a rule, in a circular sent to all the medical men in this town, that a judicial remit is justifiable only when there is an absence of such characteristics, or "facts or rumours connected with the death pointing to criminal blame". No such facts or rumours, as far as I know, existed in the case under discussion. But even admitting the grounds you go on, I cannot allow that the Fiscal followed a *courteous* mode of procedure; and I think the majority of my professional brethren will agree with me. It is true that the Fiscal has a right "to nominate whom he pleases to conduct the examination"; but I think the queries addressed by me to Dr. Littlejohn of Edinburgh (the principal medico-legal adviser of the Crown in Scotland), and his replies, show very clearly that, in Edinburgh at least, in a similar case to this one a different course would have been followed. You are also mistaken in saying that the examination was made "under the superintendence of" Professor Ogston. That gentleman never even saw the dead body. His only connection with the case was, that a remit to make a *post mortem* examination was made to him, and that he *did not* carry that remit out.—I am, yours truly, ANGUS FRASER, M.D.

Aberdeen, February 11th, 1878.

\* We have not misunderstood, and we trust we have not misrepresented, Dr. A. Fraser's complaint. Had the Fiscal directed him to make the *post mortem* examination, we should have heard nothing of the case. As it happened, the order or remit was sent to another medical man without any intentional slight to our correspondent; and, as no objection is made on this point, we infer that the *post mortem* examination was properly and satisfactorily conducted. If the Fiscal knew that Dr. Fraser had seen the body of the deceased, and that he had already made an arrangement with the widow to inspect it, it would have been courteous on his part to have consulted Dr. Fraser on the subject before sending a remit to another professional man. It seems to us, however, that the Fiscal and Dr. Fraser acted in ignorance of each other's proceedings.

#### PROFESSIONAL FEES.

SIR,—In reply to your correspondent on the above subject, I contend that the patient who sends for a doctor a long journey should pay the fee for such, and that any others requiring attention in the vicinity should pay according to the distance from the patient first visited, the medicines for both being at the usual rate, as given by Mr. James Brown. I consider, however, that it is unadvisable to meet in consultation below double the ordinary charge for a visit, and equally so to visit even a neighbour and make no charge, unless it be an undoubted case of charity, which every medical man has opportunities for. My own fees for visits in a country town are 2s. 6d., 2s. 6d., 5s., 7s. 6d., etc., according to the supposed income of the patient, long distances being charged in proportion, and I do not think any one justified in accepting anything less in the present state of professional and social life. The compulsory adoption of any particular scale is, I trust, as impossible as uncalled for; and as an article is generally worth what it will fetch, so a doctor is often valued and appreciated according to his charge. It is not improbable that the status held by medicine among the professions, as well as in other quarters, needlessly to mention, is greatly owing to its own valuation, as shown by the active correspondence now before us upon the fees of our leaders. It is pleasing to find accusations of surcharge so seldom in our ranks, but equally disappointing to notice

the tendency of the bulk of practitioners, town and country, to value themselves at a rate lowering to the tone of any profession, and which many hackney coach societies would scorn. There are already in circulation numerous scales of fees recommended by various bodies and societies, which might be obtained through any good publisher. It needs only the will to carry them out.—I am, sir, faithfully yours, A RURAL PRACTITIONER.

#### SORE NIPPLES.

SIR,—I would recommend your correspondent to try during lactation Dr. Blacquire's remedy, of ten grains of extract of rhubarb, with one hundred and fifty of cocoa-butter.—Your obedient servant, W. WADSWORTH LUSH, M.D. Weymouth, January 30th, 1878.

SIR,—In reply to E. R. S., women who have small nipples, with numerous folds of thin delicate epidermis at the base and tip, are much more prone to chaps than those whose nipples are smooth, prominent, and well developed. These folds are frequently bridged over by cakes of colostrum and dirt, which render them still more tender; and, on separating them out, one may generally discover moist red spots, which are very painful on pressure, and readily give way to chaps when the cakes are removed and the folds opened up their entire length by the child's struggles with the short nipple. The prophylactic treatment, therefore, consists in hardening the epidermis, removing the folds, and making the nipples as prominent as possible; and to obtain these results, it is best to begin some few weeks before the end of pregnancy. The nipples may be rendered prominent and smooth by being occasionally drawn out with the fingers or sucking glasses; and the epidermis becomes less delicate by being kept clean and dry, and being frequently washed in cold water and spirits of wine; and during lactation more especially should it be carefully dried each time after use. If, however, in spite of all this, chaps do form, I have found no treatment equal to passing a sharp point of nitrate of silver well down to the deepest portion of the chap and freely cantering it all round, and then giving the nipple as long a rest as possible. In addition to the caustic, which should be used once a day, a little glycerine and tannic acid may be applied; and the nipple should be well washed before the child is again put to the breast.—Faithfully yours, JAMES MURPHY, M.D.

# A LECTURE ON RHYTHMICAL HYSTERIC CHOREA.

BY PROFESSOR CHARCOT,  
Physician to the Salpêtrière Hospital, Paris.\*

HAVING recognised the case which now occupies our attention as a well-marked example of rhythmical chorea, we must now show that the title of hysterical is further applicable to it; or, in other terms, that the choreiform affection is here under the influence of an anterior malady—hysteria—of which it represents one of the multiple and varied manifestations. To establish the existence of the hysterical basis in our patient will be an easy task; the proofs in support of our assertion will be found in abundance.

The study of her antecedents teaches us that in G. convulsive hysteria began to manifest itself from the age of thirteen. We have seen this young girl present daily in this hospital for a period of two years, from about the age of fifteen to seventeen, and, in the most marked fashion, the permanent local symptoms of the form of hysteria which we propose to call ovarian, although menstruation had not yet appeared. The appearance of the menses, which took place about two years ago, has not modified the clinical picture in any essential respect. The convulsive paroxysms and the local phenomena have persisted as before, and I will presently prove to you their actual existence. I might cite to you several other cases of ovarian hysteria developed several years before menstruation; and, on the other hand, I shall presently show to you two women in this hospital in whom the hystero-epileptic crises, as well as the series of symptoms of local hysteria which are almost inevitable in such cases, have persisted, without any other modification than a slight diminution, for several years after the occurrence of the menopause. These facts in the pathological domain agree, I may remark in passing, with the physiological facts, which are now numerous, tending to demonstrate that the activity of the ovary is far anterior to the menstrual function, and survives it.†

Here is the enumeration of the principal symptoms of local hysteria, of which the presence may be actually recognised in our patient. There exists an *ovaralgia* or *ovaric* on the right side, very distinctly marked; the pain by which it is manifested is fixed, always present in a certain degree, and is spontaneously increased at the approach of the attacks. At all times, it is increased by pressure. It is at this painful point that the sensation of premonitory aura of the attacks seems to take origin, ascending then to the epigastrium, præcordial region, neck, head, etc. All the right side of the body—head, neck, and trunk and limbs—is in a state of complete, absolute anaesthesia. You see, in fact, how a large and not well-pointed needle may be passed through thick folds of the skin of the forearm, of the nape of the neck, of the leg, and of the interdigital folds of the right hand, without the patient having the least idea of what is being done. On the right side, there is also thermo-anaesthesia; and, further, the special senses are also all affected, although in different degrees.

There are anosmia in the right nostril; absolute loss of taste in the right half of the tongue from the point to the base; diminution of the auditory power of the right ear; amblyopia with dyschromatopsia of the right eye. In this eye, G. has completely lost the perception of colours called central—violet and green; while she still distinguishes quite clearly the peripheral colours—red, orange, yellow, and blue. To this hemianæsthesia corresponds, as is usual in such cases, a certain degree of hemianæsthesia. Thus, whilst for the left hand the dynamometric pressure is 25 kilogrammes (nearly 54 lbs.), it is represented for the right hand by only 15 kilogrammes (a little more than 32 lbs.).

Let us take the opportunity of noticing once more the remarkable concordance, on which I have many times insisted, between the seat of the iliac pain and the mode of localisation of the concomitant symptoms. The ovaralgia is seated on the right side; and it is the right side that suffers from anaesthesia and cachexia. It is also on the right side that in G. is manifested the contraction of the limbs when it follows the attacks; and you have been able to observe that it is the limbs of the right side that are to-day agitated by rhythmical

choreiform movements. It is at least very probable that these phenomena would occupy the left side of the body, if the ovaralgia were seated on the left.\*

I limit myself to this summary exposition, and I spare you the details which my previous studies on the subject will have already brought before you. My object has been only to show you that, so far as concerns the local symptoms, the case of G. is a very regular, very classic example in the category of ovarian hysteria. There, however, is still one point upon which I desire to comment an instant, because it relates to some questions now under discussion. Our patient, to speak the language of Dr. Burq, is a polymetallic hysteric. She is sensitive to gold and to tin; that is to say, if you apply to her, in any region of the anaesthetised parts, either a plate of tin or some pieces of gold, you find, at the end of ten or fifteen minutes from the application, that sensation has returned in all its forms, not only under the metallic plate itself, but also above and below it within a certain limit. There are, you know, according to the observations of Dr. Burq—observations now recognised as perfectly accurate at least on this point—hysterical persons who are sensitive exclusively to gold, others to iron, others to copper, or zinc, or silver. There are also—as you see here, for example, under our eyes—polymetallic hysterical persons; that is to say, sensitive to several metals. The fact of being influenced in the manner just indicated by the simple metallic application is not, contrary to the opinion hitherto expressed by Troussseau, a character exclusively peculiar to the hemianæsthesia of hysterics. We have seen, in fact, two cases of complete cerebral hemianæsthesia of old date connected with an organic lesion, in which applications of metals have, as in hysteria, had the result of causing the return of normal sensibility. But whilst in these two cases the results have been definite and permanent, so far that they still exist at the end of more than a year, they have always been transitory in the cases of hysterical hemianæsthesia which we have observed. In cases of the latter kind, half an hour, two hours, or twenty hours after the pieces of metal have been removed, the anaesthesia returns just as it was before the application. This very mobility, this transitory character of the phenomena, is perhaps a feature which really distinguishes hysterical hemianæsthesia from cerebral hemianæsthesia of organic origin.

So far as results to the convulsive crises, I shall limit myself to saying that in this matter also G. may be considered as a true subject for study. In her, in fact, the diverse phases which, according to the description that I have given you, make up the hysteric epileptic attack in its type of complete development, succeed each other with remarkable regularity: 1. A phase of generalised epileptiform convulsions terminated by a short period of stertor; 2. A clonic phase *par excellence*, consisting of extensive movements of the body—of contortions; 3. A phase of attitudes, of passions, or, if you prefer it, of *poses plastiques*. The period of consecutive delirium after the crises, which in other subjects is so pronounced, is, on the contrary, in this case hardly noticeable. Such is the series of phenomena which constantly in all the attacks, and in the intercurrent attacks, the chain of which constitutes a state of disease, are reproduced in G. always after the same method and in the same order. I will add, finally—it is a symptom, in my opinion, of the first order—that methodic compression of the right ovarian region, provided always that it is conducted according to rule,† always immediately arrests in her the phenomena of the attack, whatever they may be, and whatever may be the period at which the manœuvre is performed.

I have said enough, I hope, to enable you to recognise that our patient, as I have already told you, presents all the characters of ovarian hysteria under the most regular, most classic form. I shall now endeavour to show you that the rhythmical chorea with which she is to-day tormented does not represent a fortuitous complication, a foreign episode in the history of a great nervous malady, but that it is attached, on the contrary, to the hysterical diathesis by very close bonds as a subordinate affection, in the same manner as paralysis and contractions and the convulsive crises themselves.

I will point out, in the first place, that the chorea began to manifest itself ten days ago, immediately after the cessation of an attack; that is to say, in circumstances in which the various motor phenomena, paralysis, and contractions of the limbs belonging to the ordinary hysterical series are frequently developed. I will further bring to your notice that the crisis, as the sequel of which the chorea has been produced, was remarkable for its short duration and the relative slowness of all its symptoms. It was not followed by that feeling of relaxation of which

\* Concluded from page 225 of last number.

† See among others on this subject De Sinety, *Arch. de Physiologie*, 1875, p. 501; Barker, *Philadelphia Medical Times*, 1874; and *Jahresbericht*, 1874, p. 723.

\* There are some rare exceptions to this rule. I have once seen hemianæsthesia occupy the left side, whilst the ovaralgia occupied the right. Dr. Barlow of London has published a fact of the same nature.

† *Maladies du Système Nerveux*.

patients of this kind generally complain when the attack has really terminated. Hence, from this point of view, choreiform agitation might be considered as the continuation, the prolongation under a new form, of an abortive hysterical paroxysm. But there is a stronger argument, as we have assured ourselves during the last few days by repeated experiments, and as you are about to ascertain yourselves *de visu*. Methodic compression of the right ovarian region has for its certain and constant result in our patient the complete arrest of the rhythmic movements. I practise the manœuvre in question. Some complaints, a swelling of the anterior region of the neck, some noisy movements of deglutition, and the protrusion of the tongue, indicate that the expected result is about to be produced. You see, in fact, the rhythmic movement of the body, then of the limbs, stop suddenly, as by enchantment. But, although delivered from the agitation to which they were just now a prey, the limbs do not on that account recover their normal functions. They have become, especially the lower limbs, the seat of considerable muscular rigidity, comparable at all points to the contraction which, I have remarked to you before, is produced every morning temporarily at the moment of waking, before the agitation renews its course.

I proposed to you just now to recognise in the rhythmic chorea a hysterical attack in some sort prolonged and transformed. Might not one now, having regard to what precedes, connect the chorea with the contraction, and regard them as symptoms of the same pathological value, as equivalents, capable of being substituted one for the other in the series of hysterical affections?

This remarkable arrest of the choreiform movements under the influence of ovarian compression is nevertheless, gentlemen, only a suspension, a truce, which lasts so long as the compression is continued; immediately that it is suspended, you see the contraction disappear and the rhythmic movements of the trunk and limbs, just now extended and rigid, recommence as actively as ever. To convince you the better of this, I repeat the compression four or five times, and each time you see the whole series of phenomena reproduced exactly as in the first experiment.

From all this, I believe I can conclude that the rhythmic chorea observed in our patient is related to the condition of the ovary in the same way as the ordinary and convulsive crises, and that it ought to take rank among the many varied manifestations of diathesis.

It is time to look at the practical side of the subject. Developed as the sequel of an attack, that is, in the conditions in which paralysis and contractions are very ordinarily manifested, may not these choreiform movements be expected to persist just as they are until the final attack, which may not occur for a long time? Is it not possible by appropriate intervention to alter the situation, to deliver the patient from the agitation which exhausts her, to restore her, while waiting for better things, to the state in which she was ten days ago. The effects of the ovarian compression on those symptoms which are due to hysteria are not always fugitive and temporary. I shall show you on another occasion that by persisting in the compression, or by repeating it at short intervals during several hours, we sometimes succeed in causing these symptoms to disappear definitely. By this manœuvre, we have often succeeded in cutting short the state of hystero-epileptic disorder, which left to itself would have been prolonged for several days. It is possible to succeed also in suddenly dissipating the contraction of the jaw, of the tongue, or of the limbs, when the symptoms have, if I may so speak, been for a long time installed.\* Success has also been attained in putting a stop in this way to hysterical dumbness which had lasted already for several months.† Analogy leads us to think that prolonged and repeated ovarian compression would, without doubt, have the result of causing the permanent disappearance of the rhythmical convulsions. This shows, gentlemen, that in the effects of this manœuvre we have not only a means of diagnosis, an element capable of clearing up the theory of the disease, but also a therapeutic means; its practice is, however, difficult and not very suited to use. Moreover, it is not the only means to which we have thought of having recourse in the present circumstances. According to our observations, the application to the ovarian region of a bag of ice during half an hour, and repeated several times a day for several days, has often the result of arresting the attacks or lessening their intensity. But the effect of these applications is generally slow in production, and the results obtained are not always very striking.

It will be preferable, I think, to have recourse either to the inhalation of ether or of nitrite of amyl. The effects of the inhalation of

ether in hysterical patients have something peculiar. They have not yet been much studied, but certainly deserve to be well known. In certain subjects, for example, such inhalation may, by the production of unequivocal symptoms, reveal the disease which has hitherto remained latent; in others, in which it is, on the contrary, in full activity, we have seen it determine sometimes one and sometimes another phase of the attack, and sometimes the whole series. Now, an attack at a given moment in a hysterical patient may play the part of a favourable crisis, and bring about a sudden cessation of the troublesome symptoms which have, perhaps for a long time, resisted all the agents employed. In respect to nitrite of amyl employed in inhalations, it is, as M. Bourneville has shown, a means of particular efficiency in cutting short, promptly and definitely, a state of hystero-epileptic disorder, even when it presents itself under the most marked form. For this reason, it appears to us rational to propose, the trial in the present case. We shall have recourse to ether first, then to nitrite of amyl, if the former fail; and we shall not omit to keep you informed of the results which we obtain. If we succeed, as we hope, in causing the cessation of the rhythmical convulsions, we shall have delivered our patient from the symptoms which annoy and fatigue her enormously, the duration of which, if they were left to themselves, can hardly be foreseen. That will already be something, no doubt. It is, however, clear that we shall not by that means have modified the fundamental disorder; but I do not desire, at this moment, to stop to consider the treatment of the hysterical diathesis. That is a subject which requires to be discussed at length, and which I count on having an early opportunity of specially studying with you.

It will not be difficult for you to find in medical literature a certain number of cases which you can compare with this which makes the subject of our conference. Without going farther than the contemporary epoch, I will remind you that the rhythmical chorea of hysterical persons is specially mentioned in the memoir by M. G. Séé. Trousseau has not failed to speak of it at some length in his clinical lectures, and he cites there cases which evidently belong to this category. He rightly emphasises many of the circumstances which characterise the affection, in addition to the antecedents or concomitant hysterical symptoms, the form of the symptoms—viz., specially the harmony, the regularity of the choreiform movements. He appears to attach a certain diagnostic importance to the fact that the patients succeed by an effort of will in lessening, or even in momentarily suspending, these movements. But this could not be recognised as an unequivocal character. You will observe, in fact, that in G., whatever may be the efforts of will which she makes at our solicitation, the rhythmical agitation of the limbs and of the trunk persist unaltered. M. Briquet, in a chapter of his treatise (*Traité d'Hystérie*, p. 420) which he devotes to convulsions arising in hysterical patients outside the period of their attacks, relates also some interesting observations on rhythmical chorea. The case of Mlle. B., in particular, shows that this affection may sometimes persist, as hysterical contraction too often does, for several years. I will quote further an observation of Dr. Murchison, related by Dr. Handfield Jones in his *Studies on Functional Nervous Disorders*. In this case, as in ours, the choreic movements were limited to one side of the body; they were interrupted from time to time by attacks in which the parts just previously agitated were temporarily seized by rigidity. The patient could, as in Trousseau's cases, moderate or arrest them by an effort of will. It seems to me useless to multiply cases.

Before terminating, there is still a point on which I ought to lay stress. I cannot say at present whether all rhythmical chorea is *ipso facto* hysterical; but certainly all chorea is not on that account necessarily rhythmic. In support of my assertion, it will suffice to present to you another patient, W., in whom, as you see, the agitation evidently enters, so far as the form of pathological movements, into the description of ordinary chorea. When she is seated, there is no rest for her; the head, the trunk, the limbs of the two sides are incessantly agitated by contradictory movements. Erect, she cannot support herself without assistance; her limbs bend, and then straighten for a moment. If she walk, she is threatened every minute with falling. The movements in question are irregular, disorderly in principle; you cannot recognise either rhythm or cadence, nor does anything recall an intentional action. In W., however, the characters of hysteria are not less pronounced than in G. Besides the attacks which present themselves here with the three great characteristic phases of hystero-epilepsy, I pointed out the permanent existence of general anaesthesia with any anaesthesia specially pronounced on the right side and of double ovarialgia, but, as you might foresee, specially pronounced on the right side. W. is a hysterical patient sensitive to zinc. I will add finally (and it is a feature of importance and which cannot escape you) that in her, as in G., methodical compression of the right ovarian region, which in this particular case must be simultaneously performed on the two sides,

\* Bourneville, *Progrès Médical*, 1877; and *Iconographie Photographique de la Salpêtrière*.

† Debove and Liouville.

has the effect of momentarily suspending the choreic movements just as it arrests the attacks.

I have, perhaps, already too long detained you over a case the like of which you will doubtless very rarely meet in practice. But the clinical observer must not disdain the exceptionally abnormal cases which furnish him with a special mode of exercising his sagacity; besides, they must not be considered in the light of mere food for vain curiosity. Many a time, in fact, they will be found capable of furnishing to the pathologist the solution of difficult problems.

## CLINICAL LECTURE

ON

### A CASE OF PHTHISICAL PERFORATION OF THE PLEURA, WITH PNEUMOTHORAX.

By GEORGE JOHNSON, M.D., F.R.S.,

Professor of Clinical Medicine; Senior Physician to King's College Hospital; etc.

GENTLEMEN,—I have now (January 7th, 1878) under my care a case in which there is very conclusive evidence that a softened tuberculous deposit in one lung has caused perforation of the pleura, with resulting pneumothorax—that is, an escape of air into the cavity of the chest. The symptoms and the physical signs which occur in connection with this serious accident are very remarkable and very interesting; and I propose now to give you a brief history of the case, as recorded by my clinical clerk, Mr. Macdonald, with some practical and explanatory comments thereupon.

G. G., aged 26, an Italian stonemason employed at the new Law Courts, was admitted into Sambrooke Ward December 26th, 1877. He came to this country two months ago. For about six weeks, he has had cough, with expectoration of phlegm and occasional slight blood-spitting. Two days before his admission, he was suddenly seized with pain in the right side of the chest and great difficulty of breathing, which confined him at once to his bed. On admission (December 26th), the respirations were 54, pulse 140, temperature 105 deg. He complained of pain below the right nipple, extending through to the back. There was frequent short cough, with scanty muco-purulent expectoration. On inspection, it was seen that, while the left side of the chest moved freely, the right side was nearly motionless. The apex of the heart was seen and felt beating in the sixth interspace external to the left nipple. The liver was felt extending at least two inches below the margin of the ribs on the right side. On percussion, the whole right side of the chest was more resonant than the left, though the resonance had not a tympanitic character. Over the whole left side, there was loud puerile respiration; while on the right side the first impression was that respiratory sounds were entirely absent; but, on careful auscultation below the nipple, I discovered at each inspiration a distinct so-called "metallic tinkling"; and some of you will remember that I then expressed my opinion that a tuberculous deposit near the surface of the lung had softened, and perforated the pleura, so that, at each inspiration, air passed into the cavity of the pleura, giving rise to the condition called *pneumothorax*. The inspiratory metallic tinkling is caused by bubbles of air bursting through a small opening on the surface of the lung into the air-filled cavity of the pleura, and there giving rise to a resonant echo. The air enters the cavity of the pleura more freely than it passes out (no expiratory sound was heard). The consequence is, that the right side of the chest has become distended with air, which pushes the heart to the left, and the diaphragm and liver downwards.

There is yet another remarkable physical sign. When the patient speaks or coughs, the voice and the cough are heard to resound with what is called an amphoric echo: a similar echo to that which is heard when we speak with the mouth over the orifice of an empty decanter, or over the bung-hole of an empty—that is, only an air-containing—wooden cask.

The prognosis was very grave. The past history—in particular the hæmoptysis—renders it nearly certain that there is tuberculous disease of the lung; and now the right lung, being compressed by the air upon its surface, has collapsed, and is thus rendered useless; in addition to this, some pus and softened tuberculous matter has escaped into the cavity of the pleura, and acute pleurisy has been the result.

The right side of the chest was ordered to be covered by a linseed

poultice, and fifteen minims of liquor morphine to be given three times a day.

On December 31st, when I saw him for the second time, the metallic tinkling sound, or amphoric crepitation, as it is better called, was replaced by a loud inspiratory amphoric blowing, most distinctly heard below the right mamma in front, and behind in the right inter-scapular region. The amphoric echo of the voice and cough remained as before. The change from amphoric crepitation (metallic tinkling) to amphoric blowing is probably to be explained by the enlargement of the opening in the pleura permitting a fuller current of air to pass at each inspiration into the cavity of the pleura. The sound is exactly imitated by blowing sideways into a decanter, or into a large metal tube, such as a gun-barrel.

January 3rd. The physical signs on the right side remain the same, except that there is some dullness on percussion extending to near the angle of the scapula, indicating liquid effusion into the pleura. On the left side, near the angle of the scapula, a dry friction-sound is heard on inspiration. Inflammation has extended from the right to the left pleura, which is now roughened by lymph.

January 27th (the day on which this lecture was given). The auscultatory signs have again undergone a remarkable change. The amphoric blowing is no longer audible, and no respiratory sound of any kind is heard over the right side of the chest; while the amphoric echo of the cough and voice continue. What is the explanation of this change? The most probable interpretation of it is, that the orifice in the pulmonary pleura has been closed by a recent exudation of lymph, by which the passage of air from the lung into the cavity of the pleura is prevented. The temperature has ranged from 101 to 103 deg. until within the last two days, when, with increasing weakness, it has fallen to 98 deg.; the respirations, from 36 to 54; and the pulse, from 120 to 140. There has been a rapid decline of strength, and it is evident that the disease must soon terminate fatally.

*Subsequent History, with a Report of the Inspection of the Body.*—Death occurred on January 8th, within twenty-four hours after the preceding lecture was given: and the following is a condensed report of the inspection which was made by the Pathological Registrar, Dr. Barrow, thirty-three hours after death.

On opening the abdomen, the liver was found to be pushed down to within an inch of the umbilicus. The convexity of the diaphragm on the right side was on a level with the ninth rib, while on the left it extended as high as the fifth or sixth rib. The heart was displaced entirely to the left of the median line. On puncturing the right side of the chest, a quantity of air escaped. The right pleural cavity contained about six pints of greenish sero-purulent liquid. The right lung had completely collapsed; its entire surface was covered by a thick layer of recent lymph; and at its base were two masses of soft lymph, the larger one being as large as a kidney. When the lung was inflated by blowing air into the trachea, no air escaped from the surface until the soft lymph had been carefully scraped off, when a circular opening large enough to admit the blunt end of an ordinary probe was discovered at about the middle of the posterior surface of the lower lobe of the lung. Through this opening, after the removal of the recent exudation, air escaped freely when the lung was inflated. On incising the lung at that spot, the opening was found to communicate with a cavity about the size of a large walnut; the cavity being partly filled by a purulent secretion, and surrounded by condensed lung-tissue. The apex of the lung was consolidated, and contained several caseous masses; but in no other part had softening and excavation occurred. The posterior surface of the left lung was partly covered by a thin layer of recent lymph. The apex of the left lung was condensed, of a greyish colour, and having a shotty feel, with here and there a small mass of caseous deposit. No other noteworthy morbid appearance was discovered.

*Subsequent Clinical Commentary on the Case.*—It will be seen that, in this interesting case, the *post mortem* appearances corresponded very exactly with the physical signs observed during the various stages of the disease; and in particular my bedside interpretation of the replacement of the amphoric crepitation (metallic tinkling) by amphoric blowing, and the final cessation of the latter auscultatory sign, seem to be completely confirmed. The phenomena of this case are entirely in accordance with Fournet's doctrine that, in cases of pneumothorax from perforation of the pleura, the phenomena of metallic tinkling and amphoric blowing will cease if complete closure of the opening be effected. Without doubt, a crepitating echo (metallic tinkling) may occur in a closed pleura containing air and liquid, as a result of the agitation of the liquid by coughing or movement of the body (succussion), or the fall of drops of liquid from the upper to the lower parts of the pleural cavity; and perhaps even, as Dr. Walshe suggests, "the echo of rhonchi in the adjacent bronchial tubes may cause tinkling" (*On Dis-*

cases of the Lungs, 4th edition, p. 156). But, for the production of a true amphoric blowing, I am firmly persuaded that a free current of air into a large cavity is essential. In all the cases in which the phenomenon of amphoric blowing has come under my observation, this physical sign has been associated with one or other of the three following conditions: 1. A large cavity in the lung communicating with a bronchus; 2. Perforation of the lung, with an inspiratory current of air into the cavity of the pleura; 3. Pneumothorax, with a fistulous opening in the chest-wall, and a consequent inflow of air during inspiration. Some of you will probably remember a boy named Ratcliffe who was under my care in Sambrooke Ward in the summer of 1875. After being tapped for empyema, he had a fistulous opening in the chest-wall for several weeks, but ultimately recovered completely. While the fistulous opening with pneumothorax continued, we heard sometimes amphoric crepitation (metallic tinkling) caused by air-bubbles bursting through the fluid secretion of the wound into the air-containing cavity of the pleura; at other times, amphoric blowing, when a fuller current of air was inspired through the fistulous opening nearly or quite free from fluid. These phenomena could at any time be temporarily suspended when the fistulous orifice was closed by the pressure of a finger or a plug of lint.

In the great majority of cases of perforation of the pleura with pneumothorax, the diagnosis is attended with little or no difficulty. The physical signs which I have before referred to, occurring in a patient who has been suddenly seized with hurried and difficult breathing and pain in one side of the chest, are in the highest degree conclusive. In some cases, however, the physical signs are not so unequivocal as in that which I have here recorded. Some years since, I had in the hospital two cases in which there was a somewhat perplexing inconsistency of physical signs. In one case, with tympanitic resonance over the lower and back part of the chest, amphoric blowing and amphoric echo of the voice and cough, there was dulness on percussion over the upper and front part, with moist rattling sounds. This was explained after death by a pretty extensive adhesion of the upper lobe of a tuberculous lung to the chest-wall. As these adhesions between the pulmonary and the costal pleurae are the chief protection against perforation, so the forcible tearing asunder of an adhesion during a fit of coughing is the most frequent cause of the accident. The other case of pneumothorax to which I referred was one in which, with tympanitic resonance over the whole of one side, a distinct, though feeble, respiratory murmur could be heard down to the very base of the lung. On inspection, it was found that the centre of the base of the lung, over a surface about two inches in diameter, was firmly adherent to the diaphragm. This adhesion prevented the complete collapse of the lung, and the descent of the diaphragm in inspiration drew a limited amount of air into the lung.

The case which we have been considering affords an illustration of the fact that perforation of the pleura with resulting pneumothorax may occur in an early stage of phthisis. Many years ago, I saw, with my old friend the late Mr. Lavies, a case in which this fatal accident occurred at a yet earlier stage. An adult male prisoner in the Westminster House of Correction, having had a cough for a few weeks, was suddenly seized with pain in the right side and distressing rapidity of breathing. There was excessive resonance on percussion over the affected side, while the normal respiratory sound was replaced by a loud amphoric blowing. The diagnosis of perforation of the pleura with pneumothorax was obvious. The man died in a few days, and in the apex of the lung was a scanty caseous deposit, the only part that had undergone softening being a piece not larger than a pea immediately beneath the perforated pleura. In all cases, perforation of the pleura with pneumothorax is attended by the sudden onset of symptoms of more or less intensity. The collapse of the lung and the consequent sudden great diminution of the vital capacity of the chest always causes more or less urgent dyspnoea. The pain and the other symptoms associated with the onset of acute pleurisy are, I believe, mainly influenced by the amount of purulent secretion which escapes from the lung into the cavity of the pleura. When a pus-secreting cavity of considerable size opens into the pleura, the escape of its contents rapidly excites intense inflammation in the serous cavity; while, on the other hand, a perforation which does not communicate with a cavity is attended with little or no pleuritic inflammation. On looking back to some notes of cases seen when I was physician to the Public Dispensary, I find that, in the case of a man whom I saw in March 1847, although he lived for five days after the occurrence of perforation with pneumothorax, no liquid in the pleura or other evidence of pleurisy was found after death. In that case, a very small perforation had occurred at the apex of the left lung in contact with a piece of softening tubercle, but not communicating with a cavity; and this, as I believe, explains the absence of pleuritic complication.

In that case, there was absence of amphoric blowing, explained, as I then believed and noted, and as I still believe, by the extreme smallness of the aperture in the pleura. The diagnosis of perforation with pneumothorax was based upon the sudden onset of pain and dyspnoea in a phthisical subject, exaggerated percussion resonance over the left side, very feeble breath-sounds and crepitation, which was attended with amphoric echo, beneath the clavicle. From this, I inferred that the apex of the lung was partially adherent to the chest-wall; and this diagnosis was verified by the *post mortem* examination.

You are aware that when there is a mixture of air and liquid in the pleura, a sudden jerk (succussion) of the patient's body when he is standing or sitting causes a splashing sound, which is easily heard when the ear is applied over the affected side. This physical sign has been known to the profession since the time of Hippocrates. We did not seek for it in our patient's case. We had abundant diagnostic evidence without it; and the patient's feebleness and suffering were so great, that it was undesirable to add to his distress by the rather rough procedure which is requisite to develop the phenomena in question. An over-zealous auscultator is in some danger of forgetting that a minute and prolonged, and especially a rough, examination of the chest may be a source of fatigue, distress, and even danger to the patient. A short time since, a case of aneurism of the aorta came under my care in the hospital. After two or three days' stay in the ward, the patient discharged himself, and wrote me an impertinent letter complaining of the repeated and prolonged examinations to which he had been subjected. This man, although he had a very serious disease, was not suffering acutely either from pain or from weakness; and I consider that he had no sufficient cause for complaint against me, or against any of you who may have examined him in my absence. I refer to the case only to remind you of the need for so tempering your diagnostic zeal with discretion, that you may avoid giving just ground for complaint even to a cautious and querulous patient, such as we sometimes though rarely meet with either in public or in private practice.

#### FEEDING VERSUS FASTING.

By J. A. CAMPBELL, M.D., Medical Superintendent, Garlands Asylum, Carlisle.

In the JOURNAL of February 2nd, the case of "the Market Harborough Fasting Girl" appears. An account of the symptoms of the malady, the treatment pursued, the result, and the *post mortem* appearances of the thoracic and abdominal viscera, are given. Now, when cases are published in the medical journals, it is understood that they may be made use of, if such be possible, discussed from all points of view, and fairly criticised. From an asylum physician's point of view, a short *résumé* of the salient points of this case, the treatment it received, and the result, a consideration of the subject of "fasting girls" generally, and some remarks on the subject of persistent refusal of food and its proper treatment, may not be out of place.

1. *The Market Harborough Case.*—Martha White had been healthy up to 1872; then she had an attack of real or feigned illness, during which she thought she could not swallow. An explanation of the mode of using, and a threat of the use of, the stomach-pump made her swallow. She recovered and went to work. In 1873, another attack is reported, which was considered principally, if not entirely, hysterical; "but, on this occasion, moral force was futile, and all we could do was of no avail". After this had gone on for some weeks, hypodermic injection of morphia and nutritive enemata were recommended, "as the girl seemed sinking for want of food". At this time, she took nothing but butter-candy, of which she sucked nearly one pound daily. In April 1874, the patient had convulsions; after which she took no food, and died on December 15th, 1877. No urine or feces were supposed to be passed for twelve months. The account of the body and the viscera examined was what might be expected. The body was very emaciated; the organs are reported to have been free of organic disease, and the stomach and intestines from contents, except that, in the stomach, there was half an ounce of dirty mucus, and from four to six ounces of the same material in the small intestine, and a few lumps of hard feces in the rectum. The urinary bladder is reported as atrophied.

In the remarks made on this case by Mr. Frederick Grant, he states that there was no difficulty of diagnosis; and that there can be no doubt that it was hysteria; and he calls attention to the singular point of the prolonged starvation.

2. *The Welsh Fasting Girl.*—In vol. ii of the BRITISH MEDICAL JOURNAL for 1869, at page 685, particulars concerning this case are to be found. It suffices for my purpose to say that, after much wonder was excited by reports of the case, four trained nurses were set to

watch the girl, in order to detect imposture, if it existed. The patient was well watched for eight days, and then died. She never asked for food from the nurses, and it was never given to her by them during this time. This girl had attacks of hysterical crying and sobbing, and went off into what was called "a fainting fit". The *post mortem* appearances stated at the inquest were that the organs were healthy; no obstruction in the alimentary canal; a small quantity of semi-gelatinous fluid in the stomach; small intestine empty; half a pound of hard excrement in the large intestine and rectum.

To my mind, these two cases were much alike, and were both cases of hysterical insanity. No one can be considered sane who, without cause, starves so as to endanger health and life. Should cases of "fasting girls" continue to crop up, I think it would be well if the subject were brought under the notice of the Commissioners in Lunacy, as, at their instance, inquiries are at times made into cases where sanity is dubious.

It is quite admitted that the standard of sanity and insanity varies much in different parts of the United Kingdom; but when, as the result of some mental change, a patient acts in such a way as to endanger his own life, or even to become a local nuisance, it would be well at least to make a careful examination into his sanity. Old ladies who keep a house full of cats in town, thinking that they have souls, find it now-a-days scarcely safe to carry out their opinions; and the race of hermits who lived in dirt and discomfort has become almost extinct by the active discharge of duty of the country relieving officers.

In the case of the Welsh girl, eight days of careful watching and the death of the girl clearly prove that even "fasting girls" cannot live on air. I think that there can be little doubt among medical men or others that human life can only exist for a short period (limited to days) without nourishment; and that, if ordinary food be taken into the system, evacuations must follow, though, of course, they may be lessened by the nature and quantity of the food, and the alvine evacuations may be at very considerable intervals. Though it may be interesting to know how long cases may exist with very little food, yet this treatment does not conduce to recovery.

In the present state of our knowledge of the vagaries, the simulations of diseases, and the moral depravity noticed in patients suffering under the hysteric state, I think that no more "fasting girls" should occur. I do not see why many cases of mental disorder should not be treated at home, and by any medical practitioners who choose to treat them; but I certainly think that the necessary physical as well as moral force should be used, and that the treatment which has proved efficacious in asylums should be applied to similar cases when treated outside.

In the JOURNAL for February 9th, I notice that another "fasting girl" is reported from Wales. Surely efforts will be made to prevent her from starving herself to death. If the patient be not rich enough to afford proper home treatment (which, to my mind, would consist principally of at least two good meals a day, and the attendance of a sensible, intelligent, strong-minded woman, who would do all in her power to help the girl to get rid of the idea of making herself notorious and ill), the proper mode to pursue in such a case would be to give notice to the relieving officer, who is bound to call in the medical officer of the union; the mental state of the patient would be inquired into, and the case sent to the county asylum.

3. *Persistent Refusal of Food.*—In this asylum, it is and has been the practice that, in all cases of refusal of food for two full days, it should be administered artificially; of course, in feeble cases, one does not wait so long. I quote the following from Dr. Clouston of Edinburgh, my predecessor in office, under whom I acted as assistant for several years:—"Forcible Feeding" (*Lancet*, November 30th, 1872): "Hundreds of patients are fed with the stomach-pump in our asylums every year, and no bad result follows to them; but quite the contrary; in a prolonged case, I have scarcely known anyone who did not take to the stomach-pump. I have myself so fed thirty patients in the last ten years, all of whose lives were probably saved by this means; ten of whom recovered, and a large number of whom gained weight during its use; one to the extent of a stone. I am sure that a thousand patients are allowed to die by the gradual process of starvation, because they are not fed in time with good full meals regularly given by the stomach-pump, for one who is injured by using it." Dr. Clouston mentions that Dr. Maclaren of Carlisle suggested to him the use of a stomach-tube made of India-rubber, like the French flexible catheters, which, he considered, would completely obviate any risk of injury even in clumsy hands. Shortly after that date, I got tubes made of this material, and have used them since and found them most satisfactory. During the last five years, thirty-five cases have been fed in this asylum; one of them for a continuous period of two years and one month. I may mention that this patient was

phthisical, and ultimately died of phthisis. She took her food herself for five months prior to her death.

Among these cases, four were hysterical cases in girls; three of them recovered, and the fourth was removed to another asylum; and three were youths in a somewhat similar state, produced by sexual causes (the latter were all discharged recovered): the principal feature of their cases being silly emotional excitement, alternating with a trance-like or cataleptic-like state, in which the patient would lie for hours, taking no notice of what went on around, and apparently unconscious of pain or discomfort, and refusal of food for considerable periods.

Considerable numbers of girls in the hysteric state, who had refused food at home, when they were brought here, and the means and manner of giving it were explained to them, have at once given in and taken their food. I always make a point of taking such patients to see another fed with the pump, if one is being fed in the house at the time.

I believe that in certain cases persistent refusal of food may be caused by disease, or by the sequelæ of former diseases. I reported in the *Journal of Mental Science* (January 1875) two cases of melancholia presenting similar mental manifestations to each other, evidently the result of visceral lesion. Great depression, suicidal longings, abdominal discomfort, and refusal of food, were the chief symptoms. Both died above sixty years of age. In one, a stricture of the large intestine was found; in the other, occlusion of the bile-duct.

In conclusion, I admit that there are three apertures by which food can be introduced into the alimentary canal (I refer to the nose, mouth, and anus), independently of the will of the patient, and a variety of instruments are available. Under any but extraordinary circumstances, I certainly prefer the use of the natural entrance, with the stomach-pump and soft tube as appliances. I however admit that rare cases may arise where the other methods may present advantages, almost solely where cut-throat or disease of the œsophagus exists. Dr. Brown-Séquard, in the *Lancet* of January 26th, 1878, records cases where nutritive enemata were employed for periods of three, six, and eight days. Two were cases of hysterical spasm of the œsophagus, and recovered. A case of severe cut-throat was treated in this asylum in 1874, and recovered. The patient was sustained entirely by enemata for twenty-one days, and only lost 1.6 lb. in weight. The case, in full, was reported by Dr. Macleod of this asylum in the *Journal of Mental Science* for July 1875.

## ON THE TREATMENT OF UPWARD DISPLACEMENT OF THE ARMS IN HEAD-LAST DELIVERY.

By GEORGE ROPER, M.D., M.R.C.P.,

Physician to the Eastern Division of the Royal Maternity Charity; Physician to the Royal Infirmary for Children and Women, Waterloo Bridge Road.

WHOEVER has had much experience in complex labours must have observed that in head-last deliveries, the upward displacement of the arms constitutes a great difficulty in the completion of delivery—a difficulty exceedingly perplexing to the operator, very painful to the mother, and often making the difference between life and death to the child. Smellie had observed this difficulty, for he says, "If one of the child's arms, instead of being placed along the side of the head, is turned in between the face and sacrum, or between the hind head and os pubis, the same difficulty of extracting occurs as in a large head or a narrow pelvis" (McClintock's edition, New Sydenham Society, vol. 1, p. 309). This upward displacement of the arms is at times attributable to the unskillful procedure of the operator, who, from eagerness to expedite delivery, for the purpose of saving the life of the child, brings about this very difficulty, which to a fatal degree retards delivery. Such an accident, however, frequently occurs independently of unskillful treatment. I believe it unavoidably occurs in breech-cases, and in cases of podalic version, when the child is of an unusually large size, rendering the case one of disproportion; so that we have a large child with a large head *plus* the arms upwardly displaced jammed in the pelvic brim.

The upward displacement to which I refer is one of such degree, that the arms are so entirely extended above the head, after the trunk is born, that only the anterior folds of the axillæ can be felt, tightly stretched, and it is simply impossible, without injury to the child, to get down an arm. My chief object in remarking on this difficulty is to call attention to a very simple contrivance by which it is to be prevented. It consists in passing a noose of narrow tape round the wrist of the child. In presentations of the upper extremity, when an arm can easily be secured, this can be done at once. In the severe forms of breech-presentations, as where the legs are extended on the thighs, or where podalic version is to be effected in head-presentations, the

tape must then be passed up on the fingers of the operator, and placed on the child's wrist *in utero*. This, of course, is not so easy as when the arm is down in the vagina. For snaring an arm *in utero*, I pass the tape through a tube of flexible metal; the arm is thus more easily caught; and when the noose is securely fixed round the wrist of the child, the arm can be brought down by traction on the tape at any period of the labour. When one arm is thus brought down, the other can easily be secured. The tape must always be sufficiently long that a portion of it hangs down externally after the presenting hand has gone up. Whenever delivery is to terminate head-last, it is always well to adopt this contrivance.

I am desirous of recording this little device, because I believe it is not mentioned in any of the English text-books on obstetric practice, nor is it taught in our midwifery schools. I learned it from my friend Mr. F. Gordon Brown, one of my colleagues in the Royal Maternity Charity. He obtained a knowledge of it while attending the lectures of M. Dubois, in Paris, in 1863.

## ANTISEPTIC SURGERY.\*

By S. MESSENGER BRADLEY, F.R.C.S.,

Surgeon to the Manchester Royal Infirmary, and Lecturer on Practical Surgery Owens College.

ANTISEPTICITY, like Christianity, has more professing believers than sincere disciples; still it is something for a creed to be so generally accepted in this sceptical age, and my object to-night is not to discuss the value or importance of antiseptic surgery, but rather to criticise some of the methods of carrying it out in practice. We are, perhaps, too much in the habit of confusing antiseptic surgery with Lister's name and Lister's method. Mr. Lister neither discovered the true cause of septicity, nor was he the first to suggest carbolic acid as the most convenient agent for preventing it. He has popularised the subject in the minds of surgeons, and invented an ingenious method of dressing. I do not think that more can be justly claimed for the part he has played. Years before he wrote, Pasteur had investigated and ascertained the true cause of putrefaction; and, amongst other writers prior to Lister on the subject, Jules Lemaire, in a considerable work (*De l'Acide Phénique*), insisted upon the fact that putrefaction was caused by bacteria, and that we had in carbolic acid an efficient and convenient means of destroying these organisms, or rendering them innocuous.

Again, the dry earth system of dressing advocated by Mr. Hewson of Philadelphia, the anhydrous dressings ably handled by Mr. Hamilton and others, the terebene scab-dressing recommended by Mr. Waddy, are all scientifically directed to combat or to prevent septicity. These various agents may, and indeed do, act in different ways, as I shall endeavour by-and-by to explain; but all aim at the same object—the prevention of putrefaction. The essential difference between Lister's position and that of other antiseptists lies in this: that he claims for his method an infallible and invariable result.

Lister does not deny that other plans may occasionally succeed; but he does deny to them the certainty of success which he claims for his own. He may be represented not unfairly as saying: "Of course, a patient dressed according to my method may die; he may die of hæmorrhage, or of shock, or of embolism, etc.; but he shall not die of putrefaction or any of its effects, such as septicæmia." Now, gentlemen, the object of this paper briefly is to consider whether Lister's plan is entitled to this unique position.

And here, I think, it becomes necessary for us to discuss a little in detail the true cause and nature of putrefaction; for, though putrefaction does not necessarily include septic poisoning, no form of septic poisoning can occur without previous putrefaction.

There are two theories by which putrefaction is explained: the chemical theory and the germ-theory. The chemical theory is thus described by Neudorfer, from whose recent work, *Die chirurgische Behandlung der Wunden*, I make the following free translation. "Such albuminous bodies as blood, serum, and lymph possess a very unstable chemical constitution, and are only capable of resisting change whilst contained within their proper vessels. As soon as these boundaries are passed, they undergo molecular change, fermentation, and decomposition. As exciters of these changes, we must regard:—

1. All altered albuminous bodies which belong to the animal kingdom, since they have the property of inducing this molecular change and decomposition in unchanged albuminous bodies with which they come in contact; 2. Altered albuminous bodies met with in the vegetable

kingdom, such as lint, cotton, charpie, and other surgical appliances; 3. Water, even distilled water, coming into contact with albuminous matter, induces the changes above referred to; 4. Mechanical causes, such as blows, etc.; 5. Dynamic causes, like pain, etc." (Page 154.) Such, shortly, is the chemical theory of putrefaction, concerning which I shall content myself with saying that this explanation is no explanation at all, since the changes referred to by Neudorfer never occur unless there is some means of access for the air. Keep out the air, and these unstable albuminous bodies never do putrefy. They may escape from their boundaries; they do escape every day in simple fractures and other subcutaneous injuries, yet we confidently predict that there will be no putrefaction; for we know that, without a *primum movens*, these fluids are incapable of change. Neudorfer himself admits as much when he speaks of these changes being excited by other albuminous bodies which have themselves already undergone a change. This fact led observers to examine the air, and to inquire whether it was the air itself, or something in the air, which induced the putrefactive change; and ere long it was discovered that, if the air were carefully filtered, putrefaction never occurred. The search for this *tertium quid* led on to the detection and indictment of bacteria as the *vera causa* of putrefaction. This naturally leads me, then, to consider the second theory of which I spoke; viz., the germ-theory of putrefaction. It is true that as yet there is a link missing. We know, from the beautiful experiments of Tyndall, that air optically pure is incapable of producing putrefaction; we know that, wherever there is putrefaction, there are bacteria; but the origin of these organisms, the germs of the bacteria, are beyond our ken, and, from what I know of the matter, are likely to remain so. This, however, no more proves their non-existence than the apparent identity of embryological cells proves their similarity: the facts equally point to the conclusion that our vision, even aided with the microscope, is very limited.

Permit me to dwell for a few moments upon certain points in the life-history of these little organisms. And, first, I would remark that, like the higher animals, they are a mixed lot; sheep and goats are to be found amongst them. Of them, it may be truly said, "By their fruits shall ye know them"; for, while some are innocuous to the human system, others are lethal, giving rise to various specific diseases. Already the microscope has done much towards branding the various kinds of bacteria; much more, however, remains to be done in this direction.

The important fact for us to bear in mind in connection with the matter in hand is this: that, while some are harmless and others are harmful, all alike are capable of producing putrefactive change. Such tiny things as bacteria are, of course, difficult bodies to study; but we have learnt some important principles of their mode of living: *inter alia*, we know that they multiply exceedingly; we know that they prefer swimming to flying; we know what will kill them and what will keep them alive, and, of course, it is the study of this last fact that has led to the elaboration of antiseptic surgery. Bacteria depend, like we do, for their sustenance upon oxygen; but, like us again, they can only bear a certain quantity; too much kills them, and, for this reason, ozone is a powerful germicide and true antiseptic. I will, with your permission, refer to an experiment with this body, which I made last year in company with Mr. Harrison.

On February 5th, 1876, we took these two bottles, each containing some turnip-water just passing into putrescence; through the one, a stream of ozone was passed; in the other, the air was left untouched. Through each cork, bent tubes were inserted. These bottles are now before you. The fluid through which the ozone was passed is little changed; the fluid in the other is green and thick. I have little doubt that the turbidity of the ozonised solution would have been quite obviated, if, instead of corks, we had used plugs of cotton-wool, and so filtered the air which subsequently found ingress to our bottle. This experiment may, however, be taken as sufficient evidence of the antiseptic properties of ozone, and it is by virtue of their ozone-evolving properties that some agents employed in surgery have antiseptic powers; for example, Dr. Angus Smith informs me that all the essential oils give off ozone, and he has proved that they all possess antiputrescent properties. Of these, he tells me the oil of mustard, the oil of bitter almonds, and the oil of the eucalyptus globulus are the most powerful; and with these I intend to experiment. From recent investigation, indeed, it would appear that the eucalyptus globulus (I mean the tree itself) really merits its character of malaria-killer. May we not fairly infer that this is due to the ozone given off from its fragrant leaves? It has sometimes occurred to me that the sacred groves of Scripture had a similar value; if so, we may readily understand that the heathen's god would avenge the desecration of his temple, when these groves were destroyed, by sweeping as a pestilence over the land. Turpentine owes its antiseptic properties

\* Read before the Manchester Medical Society.

to a similar cause. I do not know whether this is true of tincture of benzoin, but think it very likely.\*

So much for the effects of too much oxygen upon bacteria; destruction equally awaits them if they get too little: by the one process, they are killed; by the other, they are starved: *voilà la différence*. It is on this latter account that all hydrocarbons, such as the fixed oils, are antiseptic, and, therefore, good surgical dressings; likewise it is by starvation, I imagine, that the anhydrous system of dressing wounds secures such immunity from putrefaction.

Turning to germicides proper, we find many substances capable of killing bacteria; boracic acid, iodine, and carbolic acid are the most in vogue. I do not know, nor do I think that it is accurately ascertained, in what proportions these substances kill bacteria; suffice it to say that, from my own experiments, I differ from Lister in saying that the No. 20 solution of carbolic acid (*i.e.*, 5 per cent. of the acid) is "as certain death to them as the gas-flame".

Before passing on to criticise Lister's special method of dressing, I wish to mention one other phenomenon attending the process of putrefaction. I refer to the evolution of ammonia. This may be taken as constant. It is true that Dr. Angus Smith, who most kindly has given me much information upon the subject of putrefaction, informs me that the presence of ammonia is not an absolute proof of putrefaction, although it comes very near it; on the other hand, he says, "its absence is to be regarded as proof positive of the absence of putrefaction". Be its origin what it may, we have these two capital facts apart from all theories: putrefaction is invariably associated with the presence of bacteria; "surgical" putrefaction is invariably accompanied by the evolution of ammonia; the microscope reveals to us the presence of the one, chemistry the presence of the other.

I am inclined to think we may go further, and say that, where we have ammonia, there we shall find bacteria; where we find bacteria, there we shall find ammonia; and, the contrary to these two propositions, where there is no ammonia there are no bacteria, and where no bacteria are present there is no ammonia. To place this entire statement, however, on the basis of proved problems, further research is needed.

I now desire to address myself more specially to that method of practising antiseptic surgery introduced by Lister, with the direct purpose of seeing if its claims to the title "antiseptic" are pre-eminent; and, first, I would inquire whether it is correct to say that this plan always defies putrefaction. It may not go for much to say that, in my hands, it has occasionally, like other plans, failed to do so; but it is a good deal to say that it fails in the hands of such a master of all the details as Mr. Lund, yet such is the case; I do not say often; I do not know whether often or seldom; but, even in his skilful and careful hands, Listerism will not always succeed in warding off putrefaction. Some little time ago, Mr. Lund undertook an operation for the radical cure of hernia. I looked upon this operation with interest, as affording an excellent proof of the value of Lister's method; and, having shortly before had a case of hernia, where I had removed a large quantity of omentum, and where putrefaction had followed, I was almost prepared to accept the superiority of Lister's plan on the score of success in this case alone. I stated as much beforehand to Mr. Whitehead, and asked Mr. Lund, at the time of operation, if he would kindly let me examine the discharges following the operation, to which request he at once acceded. The operation was a long and serious one, involving the removal of a considerable portion of omentum, and the stitching together of the pillars of the external abdominal ring. Mr. Lund himself dressed the wound on every subsequent occasion. I did not think it worth while to examine the discharge for the first week or so; but, about the eighth day, I was present at the dressing, and, at my request, Mr. Lund touched the microscope-slide I held ready with the end of the drainage-tube, which he drew from the wound. At this time, the incision had nearly healed, and the wound looked very clean and healthy, though I thought there was some detectable fetor about the pus; of this, however, it was difficult to speak, owing to the prevailing odour of carbolic acid volatilised in the spray. Under the microscope, the discharge was found to swarm with bacteria, and the patient died some days later of septicaemia. Now, gentlemen, although this is but a single case, it serves sufficiently my purpose to prove that there is no infallibility about Listerism. To admit that it does fail from time to time, even in the hands of so perfect a manipulator as Mr. Lund, is to admit that it must fail, and, therefore, its claims to our acceptance as the one true method must be based upon other grounds than its universal success.

To what, then, do we turn? Naturally, to statistics; but here we

\* Perfumes may thus come to play a part beyond "my lady's chamber"; and to surround a wound with attar of roses would be not merely æsthetical, but practical antiseptic.

are met with a difficulty. Lister himself, so far as I know, has not published his statistics, and so we must be content to compare the statistics of his followers with those of surgeons who dress on other plans. Well, gentlemen, I do not think that any marked superiority is to be made out for Lister on this score; *e.g.*, the results obtained by Callender are fairly equal to those of any follower of Lister. I would crave permission, by way of further information on this head, to quote my own statistics of amputations and excisions from January 1876 up to the present date, during which time I have employed open dressings, according to the method shortly to be described.

During the period mentioned, I find that I have had fifty-five amputations and excisions, with the following results. I only quote cases under my care at the Infirmary.

Amputations.	Recovered.	Died.	Total.
Forearm .. .. .	3	0	3
Elbow-joint .. .. .	0	1	1
Arm .. .. .	4	0	4
Shoulder-joint .. .. .	1	0	1
Hip-joint .. .. .	1	0	1
Thigh .. .. .	12	3	15
Leg .. .. .	2	0	2
Ankle .. .. .	3	0	3
Excisions.			
Elbow .. .. .	2	0	2
Hip .. .. .	2	0	2
Knee .. .. .	4	1	5
Wrist .. .. .	2	0	2
Removal of loose cartilage from knee .. .. .	1	0	1
Operation for ununited fracture of forearm. 1 .. .. .	1	0	1
Total .. .. .	50	5	55*

The important question here arises, Were any of these five deaths attributable to putrefaction or its septic consequences? and to this query I confidently reply, No, not one. The death following amputation at the elbow-joint occurred on the second day following the operation, and was distinctly due to shock, the patient, an old toper, never rallying. Of the three deaths following amputation of the thigh, one was the case of a woman, whose thigh I amputated, on account of gangrene sequential to typhoid fever, and in whose limb the artery was found blocked right up into the groin; the second was a case of diffuse aneurism, in which I had previously tied the common femoral and afterwards amputated; the man died of hæmorrhage, but the stump had healed; the third was an old Irish woman aged 72, who made a good recovery up to the third week, the stump being nearly healed, when she received bad news from home and sank. The death following excision of the knee was in a little girl of two years of age. She became sufficiently convalescent from the operation to be sent to Chesham; but I afterwards learned that she died there from, I believe, diathetic causes. Such are the statistics I have to submit to you; but you may say: Well, you have a fair percentage of recoveries; but have you not exposed your patients to greater risk than you would have done had you dressed them *à la Lister*? To this question, I scarcely know how to reply better than by submitting the temperature-charts of each patient; this, indeed, I hoped to do; but some have been lost and others I never received; what I have, however, I place before you, and I think I may say that, so far as they go, they afford no evidence of septicaemia, nor, I think, will you find amongst them one which shows an unnaturally high febrile condition as consequent upon any of these capital operations.

So much for the infallibility claim and the statistical question. I now come to positive objections to Lister's method, chief amongst which I place my objections to the spray. My objections to the spray are partly theoretical and partly practical. For some time past, I have thought it probable that the spray, instead of keeping off bacteria, really drove them into the wound; creating currents and vortices in the air, it seemed likely to me that the skirts of these little whirlwinds would be caught, and any contained microzymes entangled and driven along the lines of spray; for be it remembered the spray is not a continuous sheet of vapour, but only a good thick douche, with plenty of room for thousands of bacteria to dance between each and every atom. Many of you have seen, in the experiments with vibrating sand-plates, how the light lycopodium is caught and held in the very centre of the sites of greatest vibration, while the heavier sand is driven through into the lines of rest; similarly, I thought the bacteria might be trapped by the very means adopted to keep them at a distance.

Again, I thought the water mixed with the carbolic acid might be a fertile source of mischief; it is true the solution used is a strong one; but, as I have before mentioned, I have reason to question Lister's

\* I take this entry from my own case-book. On referring to the record of our surgical registrar, I find myself accredited with the case of a lad who died of septicaemia following amputation of the thigh. Though I have no recollection of the case, I take it to be a correct report, and wish the case to be considered along with the rest.

dictum as to the fatal effect of this No. 20 solution, as it is called, upon the lives of bacteria. Over and over again, I have seen bacteria moving as vigorously as before, after two hours' immersion in this solution. Holding these opinions, I was anxious to test their accuracy, and, therefore, I performed the following experiment.

On October 20th, 1877—that is, six weeks ago—I cut off two pieces of muscle from the leg of a girl whose thigh I had just previously amputated. One piece was removed under the spray, placed upon this board, quite new, and wiped with a sponge soaked in No. 20 carbolic acid solution, and dressed strictly according to Lister's plan. The other piece of muscle was cut off in the common air and dressed with lint saturated with glycerine and carbolic acid, in the proportion of one part of glycerine to eleven parts of carbolic acid. From that date to this, my dresser (Mr. French) has taken charge of these specimens, and dressed them each on the method first adopted about every third or fourth day. Last Friday but one, I saw them for the last time until to-night. I found the muscle dressed *à la* Lister whitish in colour, flabby, and soft; the other dark in colour, firm, dry, and semitransparent. I then Nesslerised both specimens, and found that the one dressed with the spray gave ammonia, and was therefore putrefactive, while the other gave no ammonia, and was therefore sound. Mr. French is present, and can verify what I state. I will now repeat this experiment before you, and we will note the result.

You perceive that this specimen, the Listerised one, is, as I said, pale, soft, and watery; the other is dry, firm, and nearer muscle in colour. Cutting off a piece from each, and dropping them into these portions of Nessler's solution, which you know is an exceedingly delicate test for ammonia, you notice that the first gives a brown colour, and thereby shows the presence of ammonia; the other fluid remains uncoloured, and thereby proves that no ammonia is present.\* I desire to be clearly understood in reference to the bearing of this experiment upon my argument. In my opinion, it demonstrates accurately the evil influence of the spray; but it by no means proves that these exact conditions are likely to be, or even can possibly be, imitated by so treating the living organism. You cannot, in the living subject, prevent the constant access of fresh fluids to the part, and so strictly anhydrous dressing becomes an impossibility; but it is no reason because all water cannot be excluded that we should not keep as much away as possible. It must always be remembered that two factors are needed to produce putrefaction: the seed and the soil. We will suppose, if you like, that the seed is ever present, although bacteria are much more aquatic than aerial in their habits; still, granting the presence of the seed, it will remain as the seed in the hand of the mummy, unchanged by time, until it is awakened into life by the proper soil.

It is perfectly true that it is wiser and easier, to borrow an expression of Mr. Lund's, to be *antiseptic* than *antisepic*; but, for all this, it is interesting to notice how materially you will lessen a discharge, both in quantity and putrescence, by stopping the use of water in the dressings, and mopping up the secretions with dry lint. It is, therefore, perfectly consistent and sensible to dress as nearly anhydrously as possible, although we know that the animal juices themselves form a suitable pabulum for the growth of bacteria. A more curious fact than this is connected with the influence of these organisms upon the human body, which, I confess, I am totally at a loss to understand. I refer to the fact that the effect, the septic effect, produced is in direct proportion to the quantity introduced. Recalling the extraordinary powers of multiplication of bacteria, it would seem to be a matter of indifference whether one or a million were introduced into the system; not so, however; the severity of the septicæmia is proportionate to the numbers of bacteria. The most evident proof of this is conveyed by the results of vaccination, which may be regarded as a sort of benign septicæmia, one vesicle producing very little prophylactic effects on the system as regards variola, while four or five bestow an almost absolute immunity; perhaps it is less familiar, but it is, I believe, equally true, that exactly the same holds good with what, by contrast, may be termed the lethal forms of septicæmia. These two facts taken together teach us to keep a wound as free from discharge as possible, and as dry as possible.

So much for my objections to the spray. My next objection to Lister's method is, that it tends to cover up and keep confined putrefactive matter. If you must have putrefaction, by all means have it externally; it does little or no harm, if it have free vent. Whoever heard of septicæmia caused by an ulcerated leg? Yet all of us have had unpleasant experience of ulcers so foul, of putrefying sores so extensive, that they would poison an army, if the matter were properly economised; yet the owners of these dreadful legs live and move and have

their being for years and years, with a normal temperature, a clean tongue, and a healthy appetite. One of the members here present has given me permission to mention a little circumstance which is quite *à propos*. His little girl had a trifling sore upon the eyelid, which, one day last week, scabbed over, soon after which she became feverish and ill. This state of things continued for two days, when her father removed the scab and gave exit to a few drops of pus; directly after this, she felt better, her temperature fell to normal, and, in an hour or two, she was quite well. Now, Lister's dressing is, I believe, apt to lead us into a fool's paradise: everything looks so nice and is so clean, that it is hard to believe any mischief can be lurking there, and so, while our noses are effectually hindered from detecting anything wrong by the cloud of carbolic spray, we confidently reswathe the part in the voluminous folds of gauze, etc., and perhaps leave it for a couple of days or more, during which the evil is wrought, and that may be beyond repair. It is not correct to say the drainage-tube sufficiently guards against a *contretemps* of this kind; drainage-tubes only very imperfectly guard against such accidents; it is common enough to see a stream of matter follow the withdrawal of the drainage-tube, which the latter has evidently only served to keep confined. To obviate this cork-like action, I suggested the use of vulcanite tubes which were incompressible; but, though better than the others, I cannot say they are perfect. Chiene's catgut method of drainage, which acts by capillary attraction, is perhaps the most inefficient of all. By way of illustrating this part of my argument, let me remind you of Mr. Lund's case of radical cure, which, to some extent, is the "motive", as artists say, of this criticism. His patient died of septicæmia, of which there is no outward and visible sign until the microscope is consulted, yet who will venture to say that this had not been going on for some days before detection? Again, let me recall my own case of femoral hernia, which I mentioned as having occurred about the same time, and where I had removed a large piece, a pound or more, of omentum. I do not mean to say that my case was at all comparable in gravity to his; but what I do say is this: putrefaction occurred in both; but, in my own case, the incision was kept freely open, the dressings were changed twice a day, and the patient recovered, without any septicæmic symptoms.

There are other objections to Lister's method, such as its greater expense and the inconvenience of having to keep a large stock of what may be looked upon as patent dressings on hand, procurable only through a few channels; but these are small matters compared with the two graver charges mentioned above, and with them I shall not further deal, but pass on to speak of the mode I myself employ.

It is unnecessary for me to say there is nothing original about my plan; it is necessary, however, that I describe it. In the first place, I thoroughly cleanse the skin with carbolic soap, even rubbing off the outer layer of cuticle, thus removing all clinging germs. I take care that all instruments, etc., are perfectly clean. After performing the operation, I fill the wound with some antiseptic, generally selecting No. 20 solution of carbolic acid, although many other preparations, such as chloride of zinc, or sulphate of iron, or nitrate of silver, seem to possess equal germicidal powers. I then take pains to render the wound as dry as possible, after which the sutures are introduced and the wound dressed with four or five folds of lint thoroughly well saturated in a mixture of carbolic acid and glycerine. Over all, I place either a pledget of carbolised tow, or dry lint, or cotton-wool. If the subsequent discharge be abundant, I at once liberate some of the sutures, to give free vent to the discharge, and have the wound dressed at least twice a day, otherwise the wound is dressed once a day. I carefully avoid using water in any shape or form, squeezing the matter out, not syringing it out, and wiping with dry, not with wet, lint. It will easily be understood that there are cases where the position of the pus, etc., renders it impossible to remove it altogether by pressure; this, for instance, is the case when the knee joint, or indeed any joint except the hip-joint, is opened; then it becomes necessary to wash out the discharge with the syringe. When this has to be done, I am in the habit of using a solution of permanganate of potash in preference to carbolic acid, and take care that the syringing is thorough, and performed twice in the twenty-four hours, so as to give little time for decomposition to take place. Irrigation in this case is good; indeed, is excellent; but it is somewhat messy and involves some exposure to cold, which is not always desirable or safe. There are two other conditions where the syringe comes into play, which I may take this opportunity of alluding to; I refer to the treatment of sinuses and abscesses. Speaking of the first, and supposing that all dead bone, etc., is removed from the bottom of the sinus, and that the granulation-tissue round the orifice is removed with the knife or scissors, I believe the best plan to secure closure of the entire sinus is to thoroughly flush it every day with a mixture of tincture of iodine and water (one to seven). Abscesses

\* I ought to state that on the Friday mentioned above I did not direct Mr. French to uncover or recover the Listerised specimen under the spray; therefore the experiment before the meeting did not be taken into account.

are, in my opinion, much better and more successfully treated on Calender's plan of superdistension, especially if pressure be exercised afterwards, than by the method of Lister. This at least is my experience, which in this respect, I believe, is in accord with that of some of my colleagues. You, of course, will ask me what proof I have that such a plan as the one I have detailed merits the term antiseptic equally with Lister's, and my answer is: I have given you my statistics, which, I think, will bear comparison with those of his followers; but I chiefly rely upon experimental proof.

You will please to bear in mind the two mutually supporting evidences we have of putrefaction: the presence of bacteria and the exhalation of ammonia. I make no mention of such questionable evidence as the smell or colour of the discharge.

Well, gentlemen, submitting my cases to this double test, I believe I am entitled to say that I practise antiseptic surgery; *e.g.*, among several similar experiments, permit me to mention the following. A fortnight ago, I took the first four operation cases in the female wards, and, with two of my dressers (Mr. Challinor and Mr. Pownall), examined the discharges by the double test of the microscope and Nessler's solution. The cases chanced to be an amputation of the thigh performed three weeks before, a carcinoma on the chest, a lipoma of the neck, and an excision of the elbow, all operated on ten days prior to the examination. Besides these, we examined a case of ligature of the subclavian artery with another of my dressers, Mr. Williams, in the men's wards, of a week's standing. In none of these were bacteria to be found, and in none was ammonia to be detected. But understand my position: I do not claim for this plan that it will certainly prevent putrefaction; for I know that, in some cases, putrefaction does occur, and, in my opinion, do what we will, ever will occur from time to time. What I allege of it, is that it is just as efficient as the more costly and cumbersome plan of Lister; and, in my opinion, this is no small boon. To the army surgeon, toiling in such a terrible war as is now raging, the simpler method I advocate is surely incomparably better, inasmuch as it is practical, while the other is not. But, even to the surgeon engaged in hospital and general practice, the advantage of simplifying Lister's plan is considerable; for I am daily more and more convinced that such matters as the mysterious spray, and the patent character of the dressings, act as a real hindrance to the comprehension and general adoption of the true principles of antiseptic surgery.

*British Med. J.*

## OBSTETRIC MEMORANDA.

### THE TREATMENT OF OBSTINATE VOMITING OF PREGNANCY BY DR. COPEMAN'S METHOD.

On the evening of January 25th, 1878, Mr. X. called on me, to ask me to go next day some distance into the country to see his wife, a lady aged 33, who, he said, was about two months gone in pregnancy and was troubled with constant vomiting, which had continued for the two months, and for which she had been treated by her former medical man, going up to London to stay on purpose to see him (she had lived in London till about four months since). Since her return home, however, she had become so much worse that her doctor advised her to get some one near to see her.

On the morning of January 26th, I went to see her, and found that she had never been strong; she had had five children and five miscarriages. She was somewhat stout; of strumous diathesis. It was a habit of hers to vomit on the slightest provocation; bad news would make her vomit, also her monthly periods. Four years since, the vomiting was so severe that, when she had reached eight months in pregnancy, she had become so exhausted that, as a last resource, under consultation, premature labour was procured. She had vomited during the last two months, and throughout the day and night for the last week, having no respite whatever. Once she had fainted, and several times had been quite prostrate and cold. She could keep nothing down at all; vomited every four minutes food or mucus, and, if there were nothing to bring up, simply retched violently. She looked much worn; pulse 120 (normally a quick pulse) and very feeble. I prescribed some oxalate of cerium in pill, and the usual diet in very small quantities, often repeated, and gave her an opiate at night to try to obtain some rest from the sickness. I promised to see her again in two days, so as to give the remedies a sufficient trial. On January 27th, however, at twelve o'clock, an urgent messenger arrived to summon me directly. I took with me all I needed to procure a miscarriage. I found her very prostrate; vomiting incessantly every few minutes through the day and night; she had vomited just before I entered her room, and vomited

twice during the few minutes I was then talking to her. She was so ill, and her husband had such unpleasant recollections of her former illness, when she was almost *in extremis* before premature labour was induced, that I obtained his consent to do what I thought necessary. On proceeding to examine the os, I found it very hard and cartilaginous, but I dilated it with my finger as well as I could. I then left her, begging her to take the nourishment I indicated, and prescribed some bromide of potassium, but with the understanding that I should be fetched if urgent symptoms appeared. Not expecting success, I asked to be allowed to obtain a skilled nurse for her, and made arrangements to go next day. On January 28th, I arrived at three P.M., and was rejoiced to find that, from the time I left on the previous day at two P.M., the sickness had ceased. She had eaten and slept well. This morning, she vomited once when she first put her foot to the ground for her bed to be made, but not since. She had eaten a mutton-cutlet for her lunch at one o'clock.

January 30th. I did not see her at all yesterday; but ascertained, on visiting her this morning, that she had had no return of sickness whatever, and only retched once when she first got up to dress this morning. She is able to be up and to eat fairly well, and, as the sun was shining brightly, I ordered her a little drive out; and regarding her as convalescent, at all events for the time, I have ceased to attend.

CLEMENT DUKES, M.D., B.S.,

Medical Officer to Rugby School, etc.

## POST PARTUM HÆMORRHAGE.

VARIOUS remedies have from time to time been recommended in the JOURNAL for the treatment of *post partum hæmorrhage*; but I do not remember to have seen large doses of turpentine ever advocated. Some time since, when discussing the subject with a friend, he told me he knew an old practitioner of large midwifery experience who never went to a case without taking two draughts, each containing half an ounce of spirit of turpentine; and he never knew them fail.

On February 10th, I attended a Mrs. W., aged 36, a stout woman, but of loose flabby muscular fibre. The labour progressed favourably, and the placenta came away about five minutes after the child was born. I had previously given a full dose of ergot (as she flooded last time), and kept my hand upon the uterus externally. In a few minutes, flooding commenced profusely, and continued notwithstanding the use of ergot, cold-water injections, kneading the uterus, removing clots, and keeping my hand as a plug, etc. The uterus would contract a little, then become again relaxed; the hæmorrhage continuing as badly as ever. She became cold and almost pulseless. At this stage, I gave half an ounce of turpentine beaten up with an egg; and in less than five minutes I felt the uterus contracting. It soon became firm, hard as a ball, and all flooding ceased. The patient rallied very quickly, and from that time has progressed most satisfactorily. I therefore consider the treatment by turpentine worthy of a trial, and shall hope to see the result of other cases recorded, as I feel convinced that the remedy is a good one, and to be relied upon.

JAMES POLLARD, Torquay.

## THERAPEUTIC MEMORANDA.

### TREATMENT OF DELIRIUM TREMENS.

SURGEON-MAJOR WILLIS's note on the treatment of this disease with thirty-grain doses of powdered capsicum is interesting and of much practical value. But on what therapeutic principle are we to account for the capsicum having so powerful an effect? I have recently had similar effects with less than five-drop doses of the tincture of capsicum. Can it be that in both cases the capsicum, as an acceptable and innocent substitute for alcohol, merely put the long splint, so to speak, on the patient's stomach and nervous system, thus securing his quiet acquiescence in what was for the time the *rest of total abstinence*? I confess it was with this impression that I administered the drug; but some special features of the case, and a desire to present to the patient a palatable beverage as nearly as possible in the form of his accustomed tipple, suggested the following prescription.

R. Sodæ phosphatis 5j; syrupi ferri phosphatis, syrupi limonis, aa ʒiiss; mucilaginis acaciæ ʒij; tincture cardamom. co. ʒi; aque ad ʒxxxiv. M.

Sig.—*The wine of capsicum.* A wineglass-ful as required. This was put in a common wine-bottle, and was much relished by the patient, who took it at once, and next day passed into a refreshing unbroken sleep of nearly twenty-four hours' duration.

D. TOLMY MASSON, M.D., Edinburgh.

## REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN  
THE HOSPITALS AND ASYLUMS  
OF GREAT BRITAIN.

## ST. BARTHOLOMEW'S HOSPITAL.

## CONSULTATIONS.

**JANUARY 17TH.**—*Chronic Synovitis: Suppuration within Knee-joint.*—Mr. HOLDEN exhibited in the operating theatre a girl aged 12, of very delicate appearance, fair-haired, with a pink complexion. When four years of age, her right knee was injured by a fall. She had been lame ever since. Eight months ago, abscesses formed both within and around the articulation. The suppuration, after long rest in hospital, had ceased, and the child certainly required some surgical operation, as she could not be discharged with her knee-joint disorganised, though in a state of passive disease; but Mr. Holden thought that amputation was as yet too extreme a measure, whilst he hesitated to excise the joint on account of the patient's feeble constitution. He thought that she should be sent to Margate, and excision performed at that locality.—Mr. SAVORY agreed with Mr. Holden in every particular, except that he thought it better that the girl should be operated upon in London after a prolonged visit to Margate.—Mr. SMITH believed that, if Mr. Holden directed a dresser to apply an immovable apparatus to the affected limb and then sent the child to Margate, the joint might very probably become ankylosed.—Mr. WILLETT thought that the child should decidedly be sent to Margate; but then it remained to be seen what local effect would be produced before any surgeon could determine the choice of any operation.—Mr. LANGTON was averse to excision in this case, and agreed with Mr. Smith's recommendation.—Mr. BAKER also was not in favour of excision.—It was decided that the patient should be sent to Margate for a few weeks, and her case reconsidered after her return.

**January 31st.**—*Extreme Genu Valga.*—Mr. CALLENDER brought forward a girl aged 16, who had been afflicted for several years with knock-knees. She had been ten months under treatment, but the most skilfully constructed apparatus had failed to remedy the deformity. Mr. Callender believed, as the distortion was extreme, that nothing remained but to remove a wedge-shaped portion of the lower end of the femur.—Mr. SAVORY, after referring to Vernicelli's discovery, that the internal condyle is hypertrophied in genu valgum, expressed his belief that a cutting operation might make matters much worse, and thought it would be preferable to apply an apparatus which would enable the patient to walk.—Mr. SMITH was aware that the very best results had followed removal of wedges of bone in this deformity, and believed the case under consideration to be very favourable for operation.—Mr. CALLENDER stated his determination to abide by his already expressed decision.

**February 7th.**—*Tumour of uncertain nature in Superior Maxilla.*—A man aged 65 had noticed for two years a prominence of the right side of his nose towards the cheek and inner canthus of the right eye. From the first, much mucus and matter ran from the nostril; and a year ago a surgeon removed some polypi, which relieved the feeling of tension in the nose, and the pain which had existed in the right cheek and eye. At present, the right nasal bone and nasal process of the superior maxilla are very prominent, and the eye protrudes. Both nostrils are obstructed; no swelling can be seen from the mouth, but the right nasal fossa can be felt to be completely blocked up. There is no enlargement of the lymphatics of the neck.—Mr. T. SMITH was certain of the presence of a tumour, but doubtful of its nature. If the polypi were of the simple mucous variety, the tumour might be innocent; if malignant, the growth extended so much towards the pharynx that its removal would be both difficult and dangerous.—Mr. HOLDEN recommended, as the former operation had done good, that the nose should be laid open and the cavities explored.—Mr. SAVORY felt pretty certain that the tumour was carcinomatous. He doubted that it could be extirpated entirely: if attempted, the whole right superior maxilla, if not more bone, should be deliberately removed.—Mr. MARSH was not in favour of any operation: the patient, he thought, was too old, and not healthy even for his age.—Mr. SMITH intended to represent to the patient the serious nature of his complaint, and to remove the right upper jaw-bone, if pressed to do so.

*Multiple Sarcomata in a Boy.*—Mr. HOLDEN once more exhibited this patient (see BRITISH MEDICAL JOURNAL, vol. ii, 1877, p. 807,

and p. 128 in the present volume). It was fortunate (said Mr. Holden) that the right ulna was not removed, for a day or two after the last consultation another growth was detected on the right humerus; besides, there was an enlarged axillary gland, the first evidence of lymphatic infection, no such symptom having been observed in connection with the sarcomata on the trunk and lower extremity.

*Obscure Injury to the Shoulder-joint.*—Mr. BAKER, on behalf of an old student of this hospital, practising in the country, exhibited a man that gentleman had sent to him, who had fallen nine weeks previously on his right side. The swelling of the right shoulder was so great at first that no accurate diagnosis could be made. At present, no fracture nor dislocation could be positively detected; but the patient was sent to St. Bartholomew's Hospital for the benefit of a consultation. The surgeons failed to detect any injury to the bones around the joint: there was a slight amount of synovitis, but no dislocation.—Mr. HOLDEN remarked to the students that nothing in surgery required more careful clinical examination and more deliberate judgment than injuries to the shoulder-joint. A due consideration of all negative symptoms was most important, and the diagnosis and prognosis should not be made till after consultation. These precautions were rendered all the more necessary, on account of the frequent medico-legal complications which too often occur in association with these injuries.

## REPORTS OF SOCIETIES.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, FEBRUARY 19TH, 1878.

CHARLES MURCHISON, M.D., D.C.L., F.R.S., President, in the Chair.

*Tumours of both Ovaries.*—Mr. KNOWSLEY THORNTON exhibited for Mr. TAYLOR of Guildford a specimen of double ovarian disease. There was a solid tumour of the left ovary, and the right ovary was enlarged. They came from a woman aged 60, who had suffered from colicky pains and obstruction of the bowels. The tumour became abdominal, but the obstruction became finally entire. On post mortem examination, the tumour was found flattened against the sacrum, with a coil of small intestine tied to it. The tumour was brain-like and lobulated. On section, it was found to consist of spindle-shaped cells. The right ovary had similar cells in it to those found in the ovaries after the menopause, a deposit in the meshes of the stroma; a degeneration of the structure of the corpora lutea. It was found to be a change in the coats of the blood-vessels. Organic changes were not rarely the outcome and result of functional changes. Solid tumour of the ovary is a very rare form of disease.

*Cysts from the Peritoneum.*—Mr. THORNTON showed some cysts of the peritoneum, which are so rare that no account of any is to be found in the Society's Transactions. They are stated to arise from peritoneal inflammation. They came from a married woman aged 32, who noticed an increase of bulk after a fall. They were taken for an ovarian tumour, and eight pints of fluid were evacuated by tapping. She had low fever and bowel inflammation. There was dysuria before tapping. In the left side, a hard mass could be felt behind the uterus, which was thought to be an ovarian tumour, probably multilocular. An incision was made, and a cyst was found which was adherent in front. It was tapped; in the cavity left, no intestine could be felt, and a thick membrane could be distinguished betwixt the finger and the viscera. In the left ovary was a blood-cyst. The right ovary was removed, and hemorrhage occurred from the sac. The vessels could not be tied, so the abdomen was closed. The case was dressed antiseptically, and did well; in a day or two, pyrexia set in, and the contents of the sac were let out, and found to consist of blood, sweet and not putrefying. The temperature fell, its rise being due to the tension within the sac. Cysts were found in the broad ligaments and in the layer of peritoneum over them.—Dr. WILTSHIRE inquired if any hooklets were found.—Mr. THORNTON replied that none were found.

*Cystic Disease of the Thyroid.*—Mr. JOHN WOOD brought before the Society a cyst which extended from the middle of the thyroid gland down to the middle of the sternum. It was twenty-four inches in circumference. It overlapped the sterno-mastoid muscles. It was elastic to the touch, and a large venous trunk ran over it. There was no fluctuation. The tumour could be lifted up. It moved in deglutition. The superior and inferior thyroid arteries were large and pulsating. Small hard nodular masses were felt along the veins. There was great tension in the cyst. It occurred in a female aged 28, who was pale and languid. It had existed fourteen years, and had grown rapidly of late. The cyst was emptied by the aspirator, and forty ounces of dark fluid

were drawn off. Depression of the tumour followed. The needles were connected with a galvanic battery, but the tumour re-formed. Then, thirty-six ounces of fluid were drawn off, and the cyst was injected with iodine and glycerine, but it refilled. Darting pains set in, with giddiness and palpitation; and the woman begged to have it removed. It was removed antiseptically. The operation and the after-history were described by Mr. Wood with much exactitude. The woman is now nearly well. A drawing was exhibited, which showed the manner in which the blood-vessels made their entry through the capsules of the cyst. In the interior of the cyst were found projections, probably portions or remains of old partition-walls. The lining membrane otherwise was smooth.—The PRESIDENT asked as to the histological characters of the cyst.—Mr. WOOD replied that it consisted of ordinary glandular elements, but that a more searching examination should be made.—Mr. LENNIX BROWNE said such cysts were formed usually by colloid growth breaking down.—Mr. SPENCER WATSON had met a like case, where granular corpuscles were found in the fluid removed by tapping.

*Malformation of the Heart: Large Aperture in the Septum of the Auricles.*—Dr. PEACOCK showed a specimen removed from the body of a girl aged 10, who was admitted into St. Thomas's Hospital on November 28th, 1876. She had always been a puny delicate child, and was slightly cyanotic, the lips being purple and the face flushed; but the hands and feet were not livid. She suffered from dyspnoea, and had some oedema of the lower extremities. The temperature was generally below the normal standard; a loud systolic murmur was heard more particularly at the upper part of the sternum, and a decided purring tumour was felt over a large space around the left nipple. She died on February 24th, 1877. On examination after death, the heart was of large size, but the enlargement was rather due to dilatation than to hypertrophy. The pulmonary artery was very large; the aorta, on the contrary, throughout its thoracic portion, was unusually small. In the septum of the auricles, there was an opening sufficiently large to have allowed the passage of a florin. The foramen ovale was entirely closed, and the ductus arteriosus was also impervious. There was no material valvular disease. The lungs were very dark, firm, and fleshy. The case was interesting: first, as an example of a very considerable congenital defect in the septum of the auricles, with, however, complete closure of the foramen ovale. A case very similar is reported by Rokitsky in his recent work. Secondly, it was interesting from the very slight degree of cyanosis which had existed during life, notwithstanding the very free communication between the cavities of the auricles; the slightness of the cyanosis being doubtless due to the absence of any valvular disease causing obstruction to the flow of the blood from the right ventricle.

*Imperfect Muscular Development of the Septum Ventriculorum.*—Dr. PEARSON IRVINE showed a specimen of imperfect development of the septum of the ventricles. It was taken from the body of a man aged 50, who died of phthisis, and was not known to have had syphilis. During life, the man had a systolic murmur over the left heart, this murmur not being heard in the axilla. After death, it was found that the upper part of the ventricular septum was membranous over a triangular space an inch long, with its base over the "undefended spot", which, so to speak, was unnaturally large. Here the wall had yielded into an aneurismal pouch, which projected into the right ventricle, and was big enough to admit half a large hazel-nut. One segment of the aortic valve and the large flap of the mitral were attached to the orifice of the pouch in the left ventricle, and one cusp of the tricuspid was attached to the most prominent part of the projection into the right ventricle. The aneurismal pouch was thus at that part of the ventricular septum which is last developed, and where complete imperfections are most often found. Dr. Irvine thought it likely that the aneurismal pouch was produced by the dragging of the cusp (attached in its usual position) on a membranous septum, as well as to the blood-pressure on the latter. The sac thus dragged upon had also displaced the adjacent aortic segment, and in consequence the orifice of its opposite coronary artery was completely unprotected by valve, and was distorted and dilated. The systolic murmur heard over the heart must have been due to eddying of blood-currents in the aneurismal dilatation of the membranous septum.—Dr. DOUGLAS POWELL said the adhesion of the tricuspid flap might be due to disease and not be primary.—Dr. IRVINE said that the chordæ tendineæ were not affected.—Dr. FREDERICK TAYLOR took Dr. Powell's view.—Dr. GREENFIELD took the same view, or it might be an aneurism of the undefended space of Dr. Peacock.—Dr. PEACOCK said that it was probably a malformation. The fold was expanded into a sac, and thus might be described as an aneurism.

*Thrombosis of the Vena Cava, with Secondary Thrombosis of the Portal Vein.*—Dr. SAMUEL WEST described the course of the disease

in a girl aged 17. Her legs swelled, not from the feet upwards, but generally. Then the arms and face became swollen. The left leg grew less and the right larger. Then came shivering fits, with suppression of urine, and some dyspnoea. Thrombosis with secondary nephritis was diagnosed. Ascites set in, indicating thrombosis of the portal vein. On *post mortem* examination, the diagnosis was confirmed. The abdomen was full of fluid. There was no peritonitis. The veins were enlarged, especially the anastomoses of the portal vein. A vein passing to the umbilicus was of the size of a goose-quill. There were old thromboses in the portal and mesenteric veins. The liver was small and its surface granular; the spleen was enlarged. There was an abscess behind the right kidney. There was a thrombus in the vena cava, which extended down to the common iliac. The questions which arose were these: What was the relation of the thrombus in the vena cava to that in the portal vein? and what the relation of the nephritis to the thrombus in the vena cava? He thought both were secondary. The cirrhosis of the liver was secondary to the portal thrombosis. Large granular cirrhosis of the liver is regarded as associated with portal obstruction.—The PRESIDENT said the case was one of great interest. Was there any urgent diarrhoea? In a like case he had seen, there was diarrhoea. The patient recovered after free leeching at the anus.—Dr. WEST said there was diarrhoea as a late symptom.—Sir JOSEPH FAYRER said he had seen a number of cases like this where there was malarious poisoning. The spleen became enlarged, and there was "the splenic cachexia", and thromboses were common after surgical operations and many diseases. Thromboses were found in various parts.

*Aneurism of the Right Auricle.*—Dr. WICKHAM LEGG exhibited such a lesion. It occurred in a person with emphysema and dropsy. There was a projection of the size of half a marble; it contained an old coagulum. The cavity communicated with the right auricle. There was no fatty degeneration. As to its etiology, there were two hypotheses possible: one that it was congenital, and the other that it was due to interauricular pressure on the undefended spot. It was very rare.

*Melanotic Liver.*—Dr. LEGG showed a melanotic liver which came from a female aged 39, who had an eye cut out previously for some disease, which, on investigation, was found to be a melanotic sarcoma. On *post mortem* examination, it was found that there was no return of disease in the other eye or in the brain; but there were growths in the pleura, pericardium, peritoneum, and omentum. In the liver were pigmented traces of spindle-celled sarcoma and colourless patches of round-celled sarcoma. The lower portion of the liver was the least affected. It was the largest liver ever shown to the Society, weighing twenty-eight pounds.—Mr. SPENCER WATSON asked if the first growth was outside the sclerotic.—The answer was, that it was inside.

*Ulceration of a large Biliary Calculus from the Gall-Bladder into the Duodenum.*—Mr. A. E. BARKER exhibited a biliary calculus resembling a green walnut, which was found in the ileum of a lady. It weighed five drachms, and measured four inches by four inches and a half. There were other small calculi. The duct was blocked, and the gall-bladder became adherent to the duodenum. Through this adherent part the stone had, by producing ulceration, found its way into the bowel and descended as far as the ileo-cæcal valve.

*Sequel to a Case of Cancer of the Tongue.*—Mr. LENNIX BROWNE related the sequel of the case of the patient who had been exhibited at the last meeting of the Society, suffering from cancer of the tongue invading the tonsil. Three days afterwards, he had been attacked with another violent hæmorrhage, which was somewhat arrested, though slight sanguineous oozing continued to occur for some days whenever food was taken. The patient became very weak, and the sloughing considerably extended. Early on the morning of the present meeting, he had died after a very short attack of suffocation which awoke him from sleep. Most unfortunately, a necropsy had not been permitted; but a portion of the tonsil and of the tongue were brought fresh to the Society, in order that they might be examined under the most favourable circumstances by the Morbid Growths Committee, to which they were referred.

#### HARVEIAN SOCIETY OF LONDON.

THURSDAY, FEBRUARY 7TH, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

*Gunshot Injury of the Elbow-joint.*—Mr. HORNSEY CASSON related the case of a Circassian officer, whose elbow was smashed by a Russian bullet, which lodged in the condyles of the humerus. An old servant had been vigorously sucking the wound to extract the bullet, but without success. The bullet was removed, and also the loose pieces of bone; complete resection not being attempted for want of the requisite

appliances. The case was treated antiseptically, and did well. The arm was put up at a right angle; and in six weeks there was free movement of the joint, with some power of rotation.—The PRESIDENT and Mr. MAUNDER spoke; after which Mr. CASSON replied.

*The System of Drainage existing in West End Houses, and Cases of Zymotic Diseases arising therefrom.*—Dr. FITZPATRICK read a long and interesting paper on the above subject. Diagrams showing sections of houses with their forms of drainage were used to illustrate the subject. The arrangement of West End houses are well adapted for the removal of filth, but are apt to poison the inmates with sewer-gas. Sewer-gas is a product of decaying matter, and is readily absorbed by water. It is apt to enter houses by the water-closets. In too many instances, the soil-pipe of a house passes underneath it. Frequently the waste-pipe of the cistern opens directly into the soil-pipe or drain. The rain-water pipes often enter in the same manner. By such means, sewer-gas mixes its pestilential breath with the odours of the flowers in the conservatory. Traps are used to interpose a stratum of water betwixt the house and the sewer. The D-trap is bad; is, in fact, a little cesspool. The proper drainage of a house was then described. Disconnection should always be attained; and the ventilating-pipe should be of the same diameter as the soil-pipe. Cases of zymotic disease clearly traceable to defective drainage were then related; the disease not spreading when the drainage was looked to. Six points should be attended to in sewerage. 1. Is there a D-trap? 2. Are the water-closets old and foul? 3. Is the ventilating-pipe carried to the roof? 4. Are the water and other pipes disconnected with the soil-pipe? 5. Are the drains under the house of glazed tile? 6. Is there a good syphon-trap betwixt the house and the main drain?—The PRESIDENT, Dr. BROADBENT, Mr. MAUNDER, Dr. EASTON, Mr. OWEN, Dr. SYMES THOMPSON, Mr. HORNSEY CASSON, and Dr. DANFORD THOMAS spoke; after which Dr. FITZPATRICK replied.

#### OBSTETRICAL SOCIETY OF DUBLIN.

SATURDAY, DECEMBER 8TH, 1877.

THOMAS DARBY, F.R.C.S.I., President, in the Chair.

*Fibrous Polypus.*—Dr. M'CLINTOCK exhibited a small specimen of this disease, which he had removed from one of his patients. The woman had four years previously been the subject of an exactly similar tumour, which had been removed.

*The Influence of the Uterus in Eye-Diseases.*—Mr. H. R. SWANZY read a paper on this subject. He said that most eye-diseases were dependent on some distant organs, such as the heart, kidneys, spleen, and the uterus. Up to the present, very little was known concerning the relationship existing between the eyes and the uterus. He thought that this was due chiefly to the fact of few ophthalmologists being experienced gynaecologists, and *vice versa*. The first disease which Mr. Swanzy brought under notice as having its primary cause in the uterus was iritis, occurring in young girls from about the eleventh to the seventeenth year of age—*i.e.*, within a period varying from two or three years prior to the establishment of menstruation up to two or three years after they commenced to menstruate. Mr. Swanzy was unable positively to connect this disease of the eye with the uterus, but was inclined to believe the uterus the starting-point of the iritis, for three reasons. 1. Iritis was extremely rare at such an early time of life, unless dependent on congenital syphilis, or secondary to corneal diseases. 2. He had never seen a similar case in the male. 3. When the disease was found to occur with a certain frequency at a time of life when the uterus was approaching maturity or had lately reached it, and when all other causes were excluded, the inference was fair that the uterus had given rise to the iritis. The form of iritis in all these cases was similar; there was little or no pain, and but little vascular injection of the eye or photophobia. The treatment Mr. Swanzy used in these cases was chiefly local during the acute stages of the inflammation; and, when the inflammation had subsided, he gave iron. Inflammation of the optic nerve and retina might depend on disturbances of menstruation. In 1873, Mr. Swanzy had under his care a girl aged 19 suffering from neuro-retinitis, whose menstruation was sparse and painful, and in whom the eye affection always became aggravated at the monthly periods. Cases of optic neuritis had been seen where menstrual disturbances had gone before. Von Gräfe recognised the existence of such a connection. Mooren had seen cases of neuro-retinitis after suppression of menstruation, and he was of opinion that retroflexions of the uterus and ovarian tumours might give rise to the same affection. Atrophy of the optic nerve had been noted repeatedly by Pagenstecher as occurring in women who had suffered from severe menstrual disturbances, which he regarded as the cause of the eye-disease. Retinal apoplexies were sometimes the consequences of cessa-

tion or suppression of the menses. Kopia hysteria had till lately been classed among eye-diseases, but it was now known to be nothing more than a symptom of an uterine disease. It was not a common disease; and it was only quite lately that it had been fully described by Professor Förster in his article in von Gräfe and Sämisch's new *Handbook of Ophthalmology*; and the pathological conditions of the uterine apparatus invariably found accompanying it by Professor Freund of Breslau were mentioned by him. Dr. Freund had found, by means of a large number of *post mortem* examinations of women who had complained of these eye-symptoms, that they were uniformly affected with uterine disease, which he claims to have been the first to have recognised.—Dr. KIDD considered the relationship that existed between the eyes and uterus to be most important. He said that all women had a feeling of delicacy in their eyes during the puerperal state.—Dr. MACAN thought that when the state of the uterus during pregnancy was sometimes accompanied by loss of sight, it was easy to conceive that lesser affections of the uterus might also lead to less severe disturbance of vision.—After some further remarks by Dr. MacSwiney, Dr. Henry Kennedy, and the President, Mr. SWANZY replied.

*Treatment of Post Partum Hemorrhage.*—A paper on the treatment of *post partum* hæmorrhage by the injection of hot water into the uterus was then read by Dr. ATTHILL. He said that, of course, in *post partum* hæmorrhage, the most valuable means of stopping bleeding was the perchloride of iron; but, in cases where practitioners objected to the use of this styptic, and where the perchloride could not be obtained, he strongly recommended the trial of hot water injections into the uterus. Dr. Athill approved of the routine treatment by cold in cases where a sudden loss of blood occurred in an otherwise healthy woman, but he strongly disapproved of it in cases where the patient had been debilitated by previous disease, or exhausted by frequent, though it might be small, losses of blood. He recorded the cases of two women with whom he had tried his method with the most satisfactory results. He considered that the injection of hot water powerfully stimulated the uterus to contract, and thus rapidly checked the hæmorrhage, and thought that it even acted as a general stimulant. The effect on the pulse in the cases in which he tried this method was most marked; indeed, the pulse was affected more rapidly than by the hypodermic injection of ether, and it did not flag again. Dr. Athill would give two directions to those trying the treatment. 1. The water used should be at a temperature of 110 deg. 2. The tube of the syringe used should be passed up to the fundus of the uterus.—The PRESIDENT agreed with Dr. Athill that the injection of cold water was not always reliable. He had no experience himself of the use of hot water in such cases.—Dr. KIDD thought the suggestion a most important one on account of the ease with which hot water could always be obtained.—Dr. M'CLINTOCK had occasionally ventured to follow Baudelocque's suggestion of applying warmth to the sacrum and pubes, but had never tried the injection of hot water. He was encouraged to try the method recommended by Dr. Athill, but should prefer to use the cold first, as the warmth would have an additional power of giving a shock to the uterus after the stimulating power of the cold had been exhausted.—Dr. ATTHILL replied; and the proceedings then terminated.

#### SURGICAL SOCIETY OF IRELAND.

FRIDAY, JANUARY 4TH, 1878.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

*Restoration of the Eyelid after Excision for Intractable Ulceration.*—Mr. E. W. COLLINS read a paper on this subject. He gave the following history of a case which had come under his notice. S. D., aged 68, was admitted to the Jervis Street Hospital in last March. He was an asthmatic, intemperate man. There had been no history of syphilis. He complained of a small pimple on the lower lid of his left eye. This pimple had appeared seven years ago. It was for a long time painless, but about the time of his admission it became very painful. It ulcerated in a short time. It bled frequently, and at regular intervals. This ulceration gradually spread, till the whole lid was involved. The palpebral ligament and the cartilage of the lid were engaged; this being shown by the fixity of the lid. There was no glandular enlargement. The diagnosis made was rodent ulcer. Mr. Collins determined to remove the entire lid with the knife, preferring that method to the use of caustics. On March 8th last, the operation was performed; the entire lid being cut away. On account of the deformity caused by the operation, plastic aid was decided upon. Dieffenbach's method was adopted; but, instead of making the edges of the cut straight, Mr. Collins cut them in a curved manner. A thick flap was dissected up over the wound, and the parts were then covered with salicylic dressings. Erysipelas broke out in the ward in which the man was placed, and he

was attacked; however, no harm was done, as the flap was not at all injured. The fourteenth day after the operation, Mr. Collins commenced skin-grafting the raw surface; this process was repeated every third day till the whole surface was healed. The man left the hospital in a month after admission, being now perfectly well. The cicatrix which marked the place from which the skin was taken was very slight; in fact, it was almost quite imperceptible, and it was only on very close inspection that any sign of the former condition of the lid could be guessed at. Mr. Collins then entered into the pathological conditions of the ulcer; he had been unable to examine it microscopically on account of an accident having occurred to the specimen. He did not agree with Mackenzie (who disapproved of any plastic operation after excision, especially of the lower lid, giving as his reason that, if left to itself, the deformity would be slight), as he could not imagine the deformity being slight after the removal of an entire eyelid. Mr. Collins considered that the success of the flap very much depended on its thickness and on its form, so that it might lie in its new bed without being subject to any tension.—Dr. BIGGER knew Dieffenbach, and had often seen him perform the operation. The chief feature about Dieffenbach's operations was the immense number of pins he used in fixing the flap. He considered any operation beneficial which would do away with the unpleasant appearance caused by the disease. His experience of such cases was that in all instances, no matter how well the operation had been performed, there was a narrowing of the aperture, and he considered Mr. Collins singularly fortunate in having prevented this.—Dr. KENNEDY approved of the use of caustics externally, and tonics internally. Hemlock he had seen used in similar cases with great benefit.—Mr. RICHARDSON quoted the opinion of Sir James Paget to show that no epitheliomatous cells whatever existed in true rodent ulcer.—The PRESIDENT regretted that there was a great deal of confusion and doubt existing about ulcers of the eye. He considered the term Jacob's ulcer a very wide one.

*Extraction of a Foreign Body from the Left Leg.*—A paper on this subject was read by Mr. F. F. PORTER, who gave the history of the following case. In June 1877, a little girl aged 13 came under his observation. She had been running down some stairs about six weeks before this date with a crochet-needle in her hand, when she fell, and, the needle breaking, a large portion of it was pushed into the leg just below the popliteal space. The needle could readily be felt. She had been under treatment for six weeks previously, but no steps had been taken to remove the foreign body. Mr. Porter found the position of the foreign substance by means of a magnetised needle. He cut down on it, and removed it. The case turned out satisfactorily in every way.—The PRESIDENT considered the magnetised needle a most valuable aid to diagnosis, but said that the test was such a delicate one that it was difficult in its application.

*Deformities of the Bladder, with Experiments.*—Mr. WHEELER read a paper on deformities of the bladder, and operations for their removal; and described experiments to test the length of the intervals between the absorption of medicines and their excretion by the kidneys; as well as to test the influence of certain drugs on the secretion of vesical mucus. The chief interest of this paper consisted in the history of some cases which Mr. Wheeler had under his care in the City of Dublin Hospital, in which he had operated with good results; also for a list of interesting experiments made by him, which were in every way satisfactory.—Mr. R. MACNAMARA considered the paper valuable; and moved the adjournment of the debate.

## PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, JANUARY 19TH, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Spontaneous Amputation.*—Dr. KIDD showed a remarkable instance in a hydrocephalic fetus, with double hare-lip and cleft palate. The fingers and toes on the right side were deformed. A fine cord passed across the top of the fingers of the right hand. The tips of the fingers were cut off, and the fingers had united with each other. A band of attachment passed from the dorsum of the great toe to a circular indentation above the right ankle. The contraction of the lymph was gradually causing amputation of the leg at the site of indentation. Dr. Kidd said that in this case the amputation which had taken place in the upper extremity illustrated the late Dr. W. F. Montgomery's views as to the etiology of spontaneous amputation, while that in progress in the lower extremity bore out the views held by Professor Gurlt of Berlin, who considered these amputations to be produced by the contraction of lymph-bands connected with the amnion.

*Melanotic Carcinoma.*—Dr. E. H. BENNETT presented a set of specimens of this variety of carcinoma from the sole of the foot, the popliteal space, and the groin of a boy aged 11. He had been ad-

mitted to hospital on June 15th, 1877, complaining of a painless swelling behind the left knee. It appeared that three weeks previously he had been struck in this situation by a handball at school. Closer examination showed a globular mass of greatly enlarged glands in the corresponding groin, non-inflammatory, but evidently the result of some new growth. The sole of the same foot was distended, the fascia being drawn tight. A malignant tumour had clearly developed under, and probably from, the plantar fascia. The evolution of the three tumours had, therefore, occurred almost synchronously. The affected limb at last assumed the appearance of phlegmasia dolens, although no pain was felt until a fungous condition of the swelling on the foot set in. The lad died, owing to the supervention of hectic with diarrhoea, a month after the increasing weight of the limb prevented his going about. There was no trace of thoracic or other visceral disease, although the glands up to the thorax were all secondarily engaged. The thymus gland was affected; but the mesenteric glands and those in the opposite iliac fossa were absolutely healthy. The tumours were in parts cystic in character, with spots of black pigment, which proved, on microscopic examination, to be melanotic cells arranged in the pattern of a carcinoma.

## REPORTS AND ANALYSES

AND

## DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

### SEABURY AND JOHNSON'S PLAISTERS.

MESSRS. SEABURY AND JOHNSON, pharmaceutical chemists, of 28, Red Lion Square, London, and of New York, have forwarded to us specimens of their specialities in plaisters. Their salicylated isinglass plaister, applied by wetting and spreading on strong waterproofed cotton-cloth, is alleged to possess the combined qualities of strength of material, and to be antiseptic, non-irritating, susceptible to the slightest wetting, very adhesive, quickly applied, and waterproof. They further state that it can be applied without heat, that it does not spoil in any climate for any length of time, and that it can be sold at a very moderate price—viz., five-yard rolls, eleven inches and a half wide, at six shillings; and one-yard rolls at one shilling and sixpence. It is prepared by impregnating the meshes of strong cotton-cloth with India-rubber; this adds strength to the tissue, and makes it perfectly waterproof. A solution of chemically pure gelatine is then charged with salicylic acid and spread on the waterproofed cloth, thereby rendering it non-irritating, antiseptic, susceptible to the slightest moisture, and very adhesive. From the specimens of this plaister which have been submitted to our notice, we can recommend its employment by the surgeon in hospital or private practice, as by its use the trouble, etc., of applying the ordinary adhesive plaister, with its irritant effect on many skins, is got rid of. All that is necessary to do in using it is to damp the surface with a sponge, when it adheres at once. Not the least advantage is, that it is mildly antiseptic. Next among their pharmacopoeial and medicinal plaisters in India-rubber combination may be found opium, belladonna, capsicum, blister camphorated, Burgundy pitch, mustard, and many others. The mustard plaister spread on cotton-cloth appears to be a most admirable preparation. The distinctive feature of these plaisters consists in utilising India-rubber as the basis on which they are spread, which gives them greater pliability and ready adhesion without heat or moisture, whilst the process of rendering them porous enables them to be worn a greater length of time without their becoming detached as the effect of perspiration.

### HAY'S PREPARATIONS OF GINGER.

MR. W. HAY, operative chemist, of 4, Regent's Terrace, Anlaby Road, Hull, has forwarded to us three preparations of ginger: 1. A tincture of the finest Jamaica ginger, made with great care after the formula of the *British Pharmacopœia*; 2. A transparent essence entirely free from resin, being a solution of the essential oil; 3. A resin of Jamaica ginger of the consistence of treacle. These preparations are worthy of commendation for certain special excellence, especially the resin, which possesses in a remarkable degree the pungency and flavour of ginger, a very small portion when placed on the tongue inducing, as it slowly melts away, a biting sensation of warmth, etc., in the mouth. As an adjunct to aloetic pills and compounds, or to the preparations of senna or rhubarb, it would probably usefully assist in diminishing the tendency to griping.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, FEBRUARY 23RD, 1878.

THE INFECTIVE PROCESSES OF DISEASE.

Now that our readers have had the opportunity of perusing the admirable lectures delivered by Dr. Burdon Sanderson at the London University, we may with advantage refer to some of the principal facts mentioned in them, and point out briefly the conclusions to which they lead. Those of our readers who have already made a careful study of the four lectures must feel deeply indebted to Dr. Sanderson, not only for devoting much time and energy, in order to make himself thoroughly acquainted with the mass of foreign literature bearing on the questions he has so ably discussed, but especially for stating shortly and in simple language the results of his own and other investigations: results at which many, for want of time, granting they had the inclination, would not easily have arrived for themselves.

From a careful study of the lectures, we believe that three facts of especial importance may be noted. 1. Ordinary bacteria are in themselves innocuous when introduced into a healthy organism, probably because of a colytic action of the blood and tissues. 2. When bacteria are provided with fluids, either in or out of the system, which have lost their colytic action, they, as the yeast-plant in the presence of grape-sugar sets up the vinous fermentation, by their growth and development set up fermentative changes, the result of which is the production of a virus, which, when it finds its way into the bloodstream, causes septicæmia. 3. The growth and development of specific organisms in the system cause specific diseases. Keeping these facts in mind, it is evident that it is of the greatest moment that septicæmia, in its cause and effects, be understood to be something very different from such a specific disease as splenic fever; and that the theory employed to explain the *rationale* of the latter—the theory of *contagium vivum*—is very different from the germ-theory.

Septicæmia, being the result of a virus elaborated by bacteria, a virus which does not increase in the system, is only fatal when a sufficient quantity has been introduced; whereas such a specific disease as splenic fever results from a specific organism which increases in the system, and proves fatal when it has sufficiently multiplied. Every one is now so well acquainted with splenic fever and with the already famous organism *Bacillus anthracis*, which produces it, that it would be out of place at any length to refer to it; but, as it is the first specific disease which we can without doubt or hesitation attribute to a specific bacterium, it must ever be alike interesting to the physician and the scientific investigator. Since proving that, when an animal is inoculated with the spores or rods of *Bacillus anthracis*, splenic fever is sure to result, Mr. Lister has shown that another specific organism—*Bacterium lactis*—always leads to a particular fermentation, the lactic acid fermentation; and, just recently, Dr. Klein has made out that the so-called pig-typhoid is produced by another specific organism similar in its growth and development to the bacillus above mentioned. If we have at last found a bacterium which we can see and handle, which we can watch passing through all its phases on the warm stage of a microscope, and if, at any moment, by introducing it into an animal, we can set up a distinct disease, and one only, may we not hope that, at no distant period, Dr. Sanderson may be able to tell us, in a similar course of lectures, that many of the maladies met with in every-day

practice are due to similar causes; that many of them are the result of the growth and development of specific organisms?

Dr. Sanderson, having considered the effects of septicæmia, passed on to the causes; and, we think, clearly made out that probably all but the nervous symptoms and pathological appearances accompanying and resulting from the introduction of a virus into an organism, are due to the disintegration of the colourless blood-corpuscles, leading to the formation and deposit of clots in the smaller vessels of the mucous membranes.

Another important consideration was the relation between septicæmia in the lower animals to the septicæmia we have accompanying—*e.g.*, a compound fracture in man. The chief difference is, that the virus, instead of being produced outside the system, it may be from an infusion of muscle in a glass beaker, is elaborated at the seat of the fracture and reaches the blood through the lymphatics. Here, as before, two things are necessary: in the first place, we must have tissues or fluids which have lost their colytic action; and, into contact with these, we must bring bacteria. Dead tissues alone are not enough; for, if kept free from bacteria, they remain unchanged. Bacteria alone are not enough; for, without dead tissues, they remain inactive.

This naturally leads us to the germ-theory, which teaches that putrefaction is the result of fermentative changes set up in a wound by living particles always found in the atmosphere. We may discern in the course of time that there are different kinds of putrefaction, and that each is set up by a special organism, just as the lactic acid and vinous fermentations are caused by specific ferments.

For the antiseptic method of treating wounds, no one has said so much in this country as Dr. Sanderson; but we fear much of the good which might have resulted from his strong testimony in its favour has been crippled by the statements which followed, showing that he was not able to endorse the theory on which the method has been built up. Dr. Sanderson, if we understand him aright, thinks that bacteria have not so much to do with putrefaction in a wound as the organised fluids and tissues in and around the wound itself; yet he believes that it would be impossible to have putrefaction without them, just as it is impossible to have septicæmia without them. In a fracture, compound or simple, there are always broken down tissues enough and extravasated blood enough, so that it is only necessary to allow bacteria to come into contact with these in order to have fermentative changes set up; but it seems that Dr. Sanderson believes that bacteria are always present; hence we should always expect fermentative changes to take place even in simple fractures, and that, if for a short time a wound be exposed to the ordinary air, no harm would follow; and, further, that heaping layer after layer of gauze over a wound cannot be of much use. Why endeavour to keep bacteria out when they are already present? But, if present, how is it that Mr. Lister cannot find them? How is it that clots of blood lying in the wound become organised instead of breaking down, as they always do when, even for a few minutes, they are exposed to the ordinary atmosphere?

Dr. Sanderson offers no explanation, but states that the principles which underlie success are deeper than the surface, and ventures to suggest that free drainage, in order to prevent infectivity; scrupulous cleanliness, so as to prevent the organisms from finding a convenient substratum to develop in; and, lastly, the use of disinfectants, may account for the wonderful results obtained.

Those who think with Dr. Sanderson bring forward in favour of their views the statements made by Volkmann, Fischer, Ranke, and others, which go to prove that bacteria are found in the discharges from antiseptic wounds, and say, further, that the existence of bacteria in the kidneys and other abdominal organs is inconsistent with the germ-theory.

In answer to the latter statement, seeing that healthy blood, when kept from the air, like milk, does not putrefy, and that healthy tissues have a colytic action, may they together not so act on the bacteria that enter them from the liver and kidneys, that they prevent their growth and development? May they not be looked upon as so many

layers of antiseptic gauze protecting the wound from *within*, as the gauze over the wound protects it from the bacteria *without*? If it be not so, how can we explain why one abscess should remain aseptic and free from bacteria when another abscess, only a few inches removed from it, is teeming with bacteria? And how can we explain why for months a psoas abscess should remain aseptic; for there is no drainage before it is opened, and no colytic of any kind comes into contact with the cavity of the abscess after it is opened?

After *bistournage*, there was no putrefaction unless bacteria—not a virus simply—were introduced into the blood-stream, and why then? May it not be that so many bacteria were introduced at a time that they were deposited amongst the degenerated tissues before the blood was able to render them inactive? If the bacteria were introduced some time previously to the twisting of the cord, they might be rendered inactive before a convenient substratum was provided for them, and thus no inflammation, pain, etc., would ensue.

If, then, bacteria do exist in antiseptic wounds, and if they cannot, in healthy patients, reach the wound in an active condition from within, they must come from without; but, seeing that, in absolutely aseptic cases, no bacteria are found, we must conclude that, when they were present, it is for the same reason that the most careful experimenter sometimes finds them in flasks which, had sufficient care been taken, would have remained sterile. Some time ago, one of the writers who stated that bacteria were found under antiseptic dressings, confessed that he had mistaken small innocuous particles for active living organisms. That bacteria are sometimes present even in Professor Lister's cases, we do not for a moment doubt; but their existence can generally be accounted for, and their presence is invariably accompanied with slight indications of fermentative changes; and such cases, although the results are nearly as good as need be desired, are never to be considered absolutely aseptic. From what we have seen of antiseptic cases, so called in London and on the Continent, we are not surprised to hear that bacteria are sometimes, yea often, if not always, found; that results at all approaching the best results of Mr. Lister are obtained even in the presence of bacteria, is a still stronger argument in favour of antiseptics even in a modified form.

Everyone knows that good results are obtained without following Lister's method; but, as Professor Tyndall has said, the good results are obtained because the surgeons in principle carry out or have anticipated parts of that method; but those acquainted with London hospitals know well that, notwithstanding all the care and cleanliness, pyæmia is far from being extinct.

In answer to the statements about drainage, cleanliness, and the use of carbolic acid, we must say that, in several hospitals, we have seen the freest possible drainage practised, the wounds kept scrupulously clean, and quantities of carbolic acid used, not to mention piles of gauze, and yet no better results than might have been obtained by leaving the wound exposed to the air or simply covered by a layer of dry lint. Nurses and dressers well know that the scrupulous cleanliness for which Mr. Lister so often gets credit, almost entirely exists in the imagination of those not *practically* acquainted with the method. In wards where the antiseptic treatment is not carried out, or where it is practised in a mechanical way, double the care and oft-repeated dressings at the best produce results which cannot for a moment be compared with those far more easily obtained by practising in an enlightened way the antiseptic method.

### THE CHOLERA.

THE latest news from Egypt state that cholera has ceased at Mecca and Jeddah; and that, although the disease has been carried to some as yet undetermined extent seawards towards Suez, cases have not been observed nearer to that town than the quarantine station at Tor. Indeed, it is now doubted whether any cases have occurred at Tor. It would appear to be difficult, in fact, at present, to get at the exact truth respecting the occurrence of cholera on the route of the pilgrims returning northwards by

sea from Jeddah and Yembo; but it may be taken that as yet, either owing to the measures adopted by the Egyptian Government or to the local conditions north of Yembo being unfavourable to the dissemination of the disease, cholera has not to the present shown itself in Egypt.

It is not difficult to predicate the position which this outbreak of cholera in Western Arabia will hold with regard to cholera in India. Towards the close of 1874, cholera became epidemically active in the easternmost districts of Bengal, and in the next two years (1875-76) it spread over almost the whole of Hindostan. Whilst this extension was in progress, the disease extended eastwards from India into Birmah and the countries beyond; and towards the close of 1876 it passed the north-western frontier into Beluchistan and Afghanistan. With the extension of cholera into the countries eastwards of India, the disease being then epidemic over a large portion of our great dependency, the fear arose among epidemiologists in this country that we were probably about to witness another general diffusion of the pestilence, or at least a diffusion which would involve a much larger portion of the world's surface than Hindostan. When Beluchistan and Afghanistan were invaded, the probability became greater, and a westward extension of the malady was looked for with some certainty. For it was highly improbable that a dissemination to the eastwards and the northwards would not be accompanied by a dissemination westwards. A southward extension, it should have been mentioned, involving Ceylon, took place early in the dissemination. In August of last year (1877), the first evidence of a westward extension of cholera was furnished by the importation of cholera into the Gulf of Suez by a French transport ship (the *Corraze*) coming from Saigon, in Cochin China. This ship, it was known, was but a little in advance of the fleet of ships coming from India and the Eastern Archipelago laden with pilgrims for Mecca. That the whole of these ships should escape becoming carriers of the malady which had established itself in the first instance in a French transport, seemed improbable; and those who were familiar with the subject looked anxiously for news of the meeting of the pilgrims at Mecca. Moreover, there was the probability that what had happened in Beluchistan and Afghanistan, had happened also in Arabia, namely, that cholera had extended there direct from India, imported into Hadramant or Gesneh, or both provinces. When, then, in January of the present year, the telegraph wires from Egypt flashed the news of cholera at Mecca and Jeddah, it took no one who had given heed to what had been going on in regard to cholera since 1874 by surprise. By what particular route cholera has been introduced into Western Arabia—whether by the sea-route from the Eastern Archipelago, or by the sea-route from India, Mecca and Jeddah being infected subsequently to Southern Arabia—has yet to be ascertained, and we may have to wait long for the facts.

The great day of the rites at Mecca, in the recent pilgrimage—the assembly at Arafat—occurred on the 15th of December last. The next day, the 16th—the day of “the slaying of victims”—the pilgrimage ended; and the day following the pilgrims began to return homewards. The first definite knowledge of the existence of cholera in Mecca in this outbreak that we yet have dates from December 24th; in Jeddah, from December 25th. At the former date, in Mecca, one hundred and two deaths from cholera were recorded during the day: a significant indication that there must have been a very serious outbreak at the time of the rites. In Jeddah, on the 25th, thirteen deaths from cholera were reported, showing that the disease had been most probably carried to that town by the returning pilgrims flocking into it from Mecca. During the seven days ending December 30th, four hundred and ninety-four deaths from cholera were reported in Mecca; during the six days ending December 30th, one hundred and sixty deaths at Jeddah. It is stated that the different caravans leaving Mecca to the east, west, and north, carried cholera with them. Of the southern caravans, nothing is said. The disease was carried by the northern caravans into Medina; and there, between December 31st and January 5th, one hundred and one deaths were recorded from

cholera. From Medina, the disease was imported into Yembo, where the departure of pilgrims for the opposite coast of the Red Sea and for Suez was for a while put a stop to. There is some reason to believe that, during the stay of the pilgrims at Jeddah and Yembo before embarkation, the disease in a great measure wrought itself out; but it would be premature to believe that they were wholly purged from it.

The detailed history of this outbreak in Western Arabia cannot fail to be of the greatest interest when it shall be forthcoming. Unfortunately, the state neither of the Ottoman nor of the Egyptian Government is such at the present moment as to give much hope that the outbreak will be subjected to so close an investigation as might be desired. The disturbed state of the Egyptian provinces and the condition of Turkey have had a most unfortunate effect upon the arrangements of the pilgrims held in quarantine at Tor and Yembo. There is little doubt that the provisions made for them, both as to shelter and food, have been most inadequate; and that they have in consequence been subjected to great sufferings. It is understood in Alexandria that strong protests have been made to the Egyptian and Ottoman Governments on this subject, by the representatives of the different European Governments.

#### CONTEMPLATED CHANGE IN THE CONSTITUTION OF THE INDIA MEDICAL SERVICE.

It has long been known that a measure to abolish the double medical administration of the British and India Medical Services has been incubating in India. We have reason to believe that this measure has been for some time before the authorities at the India Office, and that ere long the new scheme will be published. No one can deny that, on the face of it, it is absurd to have one set of medical advisers for the civil and military administrators for white and another for black troops, as if the general principles of sanitary science were so essentially different for the two races that separate experts were required to expound them. We have reason to believe that all the medical officers of the India services will be called on to elect whether they will serve in a civil or a military capacity. The civil medical administration will be placed under officers selected exclusively from the India services, and will have nothing to do with the military branch of the service. Those who elect to serve in the army will, as a matter of course, be under military medical officers selected entirely from the two services, British and Indian; and the troops, without distinction of race or colour, will be under one sanitary authority.

We see that some alarm has been created in the minds of the India services by a rumour regarded in India as "ominous", that all promotion is to cease pending the promulgation of the new scheme. We think the fear is groundless, and that, if any such notice have been given to the authorities in India, it has reference only to promotion to administrative rank. It would be a flagrant breach of faith on the part of the Government of India to delay the promotion of a single surgeon for one hour beyond the promised twelve years, to which the Government is pledged on the faith of a Royal Warrant, which the Indian Government, unlike the War Office and Horse Guards, have always respected. We presume that medical officers now in India electing to serve in the military branch, will do duty either with British or with Native troops, as the exigencies of the service require. They cannot, of course, against their will, be made to serve out of India; whether those who, after the publication of the new scheme, enter the India service will, on selecting the military branch, be under an obligation to serve at home, we do not know.

One thing we venture to hope is, that the Government of India will keep in mind, in framing the new scheme, so to shape it as not to injure the prestige of the service. It is notorious—we have only to look at the London and Netley marks to see it—that the India service commands the ablest men in the market; and we trust that Lord

Salisbury and his advisers will not, under evil counsel, suffer the medical service of India to be dragged into the mire pit in which, thanks to the bad faith and the cynical indifference of those in high places, the medical service of the British Army now flounders.

#### THE FACTORY ACT AMENDMENT BILL.

WE specially call the attention of our members to the unsatisfactory provisions of the Factory Act Amendment Bill affecting certifying surgeons. These provisions have been fully discussed in the papers issued in the JOURNAL of last year, and in the report of the Parliamentary Bills Committee. Among the most obnoxious of them was the proposition of paying a fee of sixpence as the certifying fee for factory children. This, it will be remembered, Mr. Lowe, in remonstrating with Mr. Cross last year on the subject, aptly described as a base fee; Mr. Cross's resolution to indulge certifying surgeons with none other than base fees has not, however, been shaken. If any of his medical or surgical constituents have any influence with him, we trust that they will not fail, at this critical moment, to write to Mr. Cross and to beg him to give some fair consideration to the claims of, perhaps, one of the most useful body of public servants, and to abstain from doing them so great an injury and offering so pitiful an insult to the profession as are implied in the existing clauses of this Bill. Mr. Lyon Playfair and Dr. Cameron will move amendments on the subject, and we hope all the members will write to their representatives asking them to support the action of Mr. Playfair and Dr. Cameron. The chairman of the Parliamentary Bills Committee has, in pursuance of a resolution of the Committee of last year, been in active communication with the latter gentlemen during the last few days, and they have undertaken respectively to impress upon Mr. Cross the amendments most desired by the Scotch and English certifying surgeons; they will, however, require all the assistance which can be given them from without as well as in Parliament.

WE have reason to know that the course which the Government will take this session in respect to Medical Reform is not yet decided.

THE St. Mary's Hospital Medical Society has issued cards for a *conversazione* on the 27th instant, at 8 o'clock.

AT an inquest held recently at Harpur Hill, it was found that only four of the jurymen, when they were requested to append their signatures to their verdict, could write their names.

A DEPUTATION from the Municipal Corporations Association waited upon Mr. Sclater-Booth on the subject of the registration of infectious diseases as practised in Bolton, with the view of giving similar powers to those possessed there to other towns. In reply, the President of the Local Government Board concurred in the desirability of such a measure, but wished to take further medical opinion on the subject.

AT a recent meeting of the Academy of Sciences of Paris, M. Cyon presented a note showing that there are intimate relations between the semicircular canals and the centres of innervation of the muscles of the eye. He considers that the sensations caused by excitations (through the otoliths) of the nerve-endings in the ampullæ of these canals serve, through movements of the head, to form our notions of the three dimensions of space.

A COLLECTION of ambulance-wagons, their sides and felt covers bearing conspicuously the Red Cross of Geneva, has been placed on the wharf of the Royal Arsenal. The ambulances are very light on their wheels, but their construction is simple compared with that of some ambulances which have been occasionally on view at the Arsenal, and they appear well calculated for hard service. The Royal Carriage Department has received an order for a number of medical service

wagons, elaborately fitted with all requisites of the surgery and operating-room adapted for field use. This carriage and its fittings have been designed and improved by the united labours of many eminent and experienced military officers and medical men.

#### THE CONJOINT SCHEME.

THERE will be another meeting of the Committee of Reference, appointed under this scheme, at the College of Surgeons, on Monday next, the 25th instant, to further consider the reports to be made to the several medical authorities on the regulations for carrying out the scheme.

#### ESSAY PRIZES.

It is a remarkable fact, as showing how little such prizes sometimes do to provoke research, that no award for the Triennial Prize of fifty guineas, offered for competition by the Council of the Royal College of Surgeons to its members, has been made since 1858, when it was awarded to Dr. George Harley. According to the *Calendar*, it appears that no dissertations were received in 1861, 1867, or 1873, and no award made in 1864 or 1870. The report for 1876 appears to have been omitted on the part of the compilers of this publication. The subject for the prize to be awarded in 1879 is "The Anatomy and Physiology of the third, fourth, and sixth Nerves, as illustrated by observation and experiment in health, and by reference to the effects of injury and disease". Candidates must be members of the College, not on the Council.

#### MANCHESTER MEDICO-ETHICAL ASSOCIATION.

At the annual meeting of this Society, held on January 24th, the office-bearers were elected for the year 1878. *President*: Peter Royle, M.D. *Vice-Presidents*: J. Thorburn, M.D.; I. A. Franklin, Esq.; C. H. Braddon, M.D.; D. Noble, M.D. *Treasurer*: J. Stone, M.D. *Honorary Secretaries*: A. Wahlisch, M.D., and J. Broadbent, Esq. *Committee*: W. H. Barlow, M.D.; E. Bishop, Esq.; J. B. Brierley, M.D.; Shelton Daly, Esq.; J. Hardie, M.D.; O. Dean, Esq.; C. J. Rix, Esq.; J. Roberts, M.D.; R. B. Smart, M.D.; W. T. Sinclair, M.D.; J. F. Tatham, M.D.; J. Watson, M.D.

#### CREMATION.

MR. W. EASSIE, C.E., read an exhaustive paper, at the Society of Arts, last week, on Cremation as practised in many parts of the Continent; and in a very able manner reviewed the work that had been done in this respect in various parts of the continent, and graphically described the apparatus and *modus operandi* of the several exponents of modern cremation. By one apparatus, cremation was completed in two hours, at the expense of three shillings.

#### THE DENTAL PRACTITIONERS' BILL.

THE Dental Practitioners' Bill was nearly carried through the second reading by a surprise on Tuesday last, Mr. Lyon Playfair having been induced to withdraw his intended opposition by an unfounded statement made to him, to the effect that the Parliamentary Bills Committee of the British Medical Association did not make any objection to the Bill. Bound by the pledge which he had given, upon this statement being made to him, Mr. Playfair was unable to oppose the second reading. Dr. Cameron of Glasgow, with whom the Chairman of the Parliamentary Bills Committee had communicated during the day, kindly rendered efficient service, with other members who were opposed to the plan of this Bill, in succeeding in defeating its second reading. Time will now be given for organising such opposition to this Bill as will, we hope, satisfy the promoters of it that they have no chance of carrying any such measure in the teeth of the wishes of the medical profession. Extensively signed petitions against it are in preparation, and will be presented before the Bill comes on again for discussion. Meantime, we advise our Branches also to petition against the measure, which proposes to degrade the title of surgeon and to lessen the dignity of the character which should belong to that title. We see that the chemists

also are taking the alarm, and they are right. This Bill proposes to put every existing chemist who has ever pulled a tooth in the position to claim the title of (dental) surgeon; and they think it reasonable that their successors in business should all have the same privilege. For that matter, if they have it, there is no reason why their successors should not have it; the latter have as much right to it as the former, and will probably make as good use of it.

#### DISEASE IN RUSSIA.

As a consequence of the want of precaution in the transport of fever-stricken prisoners and invalid soldiers from Bulgaria to the interior of Russia, it is said that the whole of the interior of European Russia is fermenting with fever, small-pox, and a deadly species of measles, and the contagion has developed in such a regular manner as to leave no possibility of doubt as to its original source. Commencing on the one side with Bulgaria, the disease follows the track of the Roumanian railways, developing in strength at each stage of its progress until, on reaching the central towns of Russia, it becomes a decided epidemic. The second line starts from Odessa, whither all the invalids from the Dobrukscha were despatched in the autumn. The third, and most virulent of all, is the Caucasian track, leading from Tiflis, with its typhus fever in every house, to Penza in the north, where disease has compelled the authorities to close all the public schools and institutes in the town. Along these three lines of evacuation, since the war began, have been conveyed more than 120,000 invalids and prisoners, all more or less stricken or infected with disease.

#### OPIUM-POISONING SUCCESSFULLY TREATED BY ATROPINE.

THE utility of our knowledge of the physiological antagonism of certain drugs received a practical illustration of a striking character on the 14th instant, at the West London Hospital. A woman had taken, as nearly as could be ascertained, from twelve to seventeen grains of opium in the form of laudanum. This was at 11 A.M. She was sick with an emetic at 11.30, after which she was sent to the hospital. Again she was made sick, had strong coffee given her, and was walked about. At 2 P.M., the respiration was rapidly failing, when Dr. Milner Fothergill made his usual visit. Being familiar with the treatment of failing respiration by the injection of atropine from his experiments performed for the British Medical Association (see the *JOURNAL* for August 4th, 1877), he determined to try a large dose at once, and had one grain of sulphate of atropia injected under the skin of the forearm at 2.15. As was the case with animals, the effect was not instantaneous, and for ten minutes the respiration fell till it became imperceptible. As the woman was becoming very cold (for with the imperfect respiratory efforts in opium-poisoning the temperature falls considerably), she was put into a warm bed, with a hot-water bottle to her feet. About ten minutes more were thus taken up, when the breathing was observed to return—about five shallow respirations per minute, with a deep sigh at intervals. The pupils, from a state of extreme contraction, became widely dilated in a few minutes. The pulse had never failed, being rhythmical, but small, at the very worst. At 4.30, the woman was breathing steadily, 13 to the minute, the respiratory act being long and deep. Her pulse was 132, full, but compressible; while her temperature was still but 97.5, showing how it had fallen. The case progressed steadily without any mishap but a small blister on each leg from the hot bottle. At 8.30, the pulse was 128, the temperature 100.4 deg., and the respirations 24 per minute. She had slept deeply. At 1 A.M., on the 15th, she was able to talk, though not rationally; the respirations 25, temperature 100.3, and pulse 120. The pupils were natural. She was rather restless at times through the night. At 10 A.M., she was conscious and thirsty, but did not complain of much dryness of the throat. The recovery was complete, and no symptoms of belladonna-poisoning ensued from the large dose given. This case will exercise a distinct influence on the future treatment of opium-poisoning; and shows, as Wood points out in his work on *Therapeutics*, that it is not the unconsciousness, but the failing respira-

tion, which is to be dreaded in this poisoning. It illustrates, too, how experiments on animals can be utilised for the benefit of man, Dr. Fothergill's experience inducing him to give the antagonist in full dose at once to arrest the falling of the respiration. The results tend to show that in many cases the atropia has been given in doses too small to be effective. The dose was large, but the results justify it. This is probably the first time that a fatal, or what is thought to be a fatal, dose of one drug has been administered at once, to arrest and antagonise the lethal action of another drug, to a human being. The case illustrates also the danger in opium-poisoning from loss of body-heat. The contrast betwixt the poor woman being dragged about, gradually chilling to a point incompatible with life, and lying in bed calmly sleeping her poisons off, was very striking.

#### SMALL-POX AT HARWICH.

ONLY one case was admitted to the Temporary Hospital last week; but, as it was one which had developed itself in the previous week, and had not been reported, it can scarcely be considered as having occurred last week; so that, in reality, no case has occurred in the town since the 8th instant, a satisfactory proof that the hospital has done its work well, and that we may not unreasonably hope for the extinction of the disease very soon. Of the sixty-two in the course of the epidemic admitted, thirty-six have been discharged cured; fourteen have died; and twelve remain in hospital, but are convalescent.

#### EDINBURGH UNIVERSITY CLUB.

THE fourteenth annual meeting of the Edinburgh University Club was held on Wednesday, February 20th, at the Grosvenor Gallery, Dr. Sieveking occupying the chair. The report of the Honorary Secretary showed that the Club now consists of 307 members; that 12 have been added to the lists during the past year; and that 5 have been removed by death. The budget of the Honorary Treasurer gave a highly satisfactory account of the present financial position. The usual quarterly dinner followed, under the presidency of the Right Hon. Lyon Playfair, covers being laid for one hundred and thirty. The Marquis of Hartington was the principal guest of the evening; and this being the first public occasion on which he has appeared before the graduates since his election as "Rector magnificus" of the University, the reception accorded him was of a peculiarly hearty and enthusiastic character. Among other visitors present were Mr. Grant Duff, M.P., Professor Huxley, Mr. Froude, Dr. Acland, Sir George Yool, Dr. Allen Thomson, Dr. Buchanan, Lieut.-Col. Holt, Professor Longmore, etc.; and most of the leading members attended to do honour to the noble Marquis in his double capacity of Lord Rector and honorary member of the Club.

#### THE JURY OF MATRONS IN CRIMINAL CASES.

WHEN shall we hear the last of this ancient method of determining the question of pregnancy for legal purposes? In the recent trial at Chester, the woman Heeson, who was proved to have destroyed by poison her mother and two of her children, pleaded pregnancy in bar of execution. Thereupon, according to the provision of the criminal law, a jury of women was taken from among those casually present in court (*de circumstantibus*); and they were sworn to try not only whether the convict was pregnant, but whether she was quick with child or not. The learned judge who tried the case very properly directed that the surgeon of the gaol, Dr. McEwen, should be associated with the twelve matrons or discreet women required by the law. He was sworn to assist the jury; and, after due consultation, they returned a verdict that the woman was with child of a quick nature; whereupon, although judgment was passed upon her, her execution was suspended until she had been delivered, and until a reasonable time after that event, or until such a time after that it is proved by the course of nature she could not have been with child at all. The law does not provide for a medical assessor to assist the matrons or mothers taken by chance on these occasions; but few judges now place reliance upon the opinion expressed by them unless it has been confirmed by the

judgment of a medical man. It would be better, in order to prevent mistakes and ensure a proper verdict, that the duty of examining a woman under these circumstances should be assigned to two local medical men nominated by the judge. A short Act of Parliament might be introduced to dispense with the services of the jury of matrons altogether.

#### HOSPITAL ADMINISTRATION.

THE authorities of the London Hospital would do well not altogether to ignore the statement of Mr. A. S. Crowder of Portland Place, that he and many other residents in the West End, well acquainted by personal experience with the wants and sufferings of the East End, are deterred from contributing to the funds of the London Hospital by the mismanagement of the out-patient department and by the want of due inquiry into the circumstances of patients relieved. The indiscriminate relief afforded by the London Hospital has a pauperising effect on the whole neighbourhood, and by none is this more strongly felt than by the most intelligently charitable persons. Some time since, the London Hospital authorities asked, we believe, the Charity Organisation Society to institute an inquiry into the out-patient relief, and we believe that they also received a report on the subject. Why is not that report published for the information of the Governors, the subscribers, and the public generally? The London Hospital is, it is said, about £20,000 in debt on the last year's operations. We appeal to its managers to put those operations beyond the reach of suspicion as to their beneficence.

#### SANITARY CONDITION OF HORSHAM.

DR. ASHBURNER has just issued a report on this town, showing that overcrowding, bad drainage, a want of proper hospital accommodation and a mortuary, are causing much injury; whilst he also says that the water-supply is largely contaminated by sewage from pigsties, refuse-pits, and cesspools; that dead bodies have to remain in the same room with the sick and healthy; and that the town is thereby brought under conditions the most favourable to the spread of epidemic diseases. We should have thought that such a catalogue of evils would have stirred up any sanitary authority, and that the local journals would have cried out loudly against such a state of things continuing; but, instead of that, the statement is met with jibes and jeers, and the low death-rate and high birth-rate of Horsham are brought forward to prove that nothing should be done. As a sample of the line of argument adopted, we reproduce the following sentence: "Very much drained towns are frequently most objectionable, whereas other places which continue their primitive systems are stubbornly healthy." Comment on such a sentence is superfluous, and we can only leave the writer to his own meditations.

#### WAR MEDICAL SERVICES.

ON no occasion, perhaps, has the services of the surgeons of the Red Cross ambulances been performed under circumstances of so much difficulty and danger, so much self-sacrifice, as during the Russo-Turkish war. We fear that the loss of life and suffering from disease among the English surgeons who have given their services in the Stafford House ambulances is unprecedented in any war. The Committee report that their surgeons in Erzeroum, Drs. Ryan, Morisot, and Williams, who were stated by last accounts to be dangerously ill, were recovering, and would be removed to Constantinople as soon as possible. The Rustchuk section was on its way to Constantinople, as the authorities at Varna stated that they have more doctors than were required. The three ambulance sections which accompanied Suleiman Pasha's army on its retreat from Philippopolis to Port Lagos arrived at Constantinople on the 3rd instant. It is very gratifying to know that not only were their ambulances able to render great assistance on the field and during the long retreat, but that many of the wounded soldiers dressed on the field beyond Samarkof were actually brought the entire way in charge of the Stafford House surgeons. At Philippopolis some wounded collected from the fight at Adakeni were trans-

ported by them to the Stafford House hospital, and left there in charge of the staff. From Semlin, Dr. Busby telegraphed on the 3rd instant to say that he was *en route* to Trieste with his party, and they would arrive in Constantinople on Monday, the 11th. The total list of casualties in the medical department of the ambulances will, we fear, be very great. The English profession have, however, good reason to be proud of the heroic manner in which these gentlemen have performed their duties, of which constant testimony has been offered by the correspondents of the papers, who have been the eye-witnesses of their devotion, as well as by the officials of both sides. They have flinched neither from pestilence nor from privation; they have never shrunk from performing their duties under fire; they have always been at the post of duty in danger, and never deserted it. We trust that a special record may be published presently of the achievements of the medical staff of the ambulance, for we are sure that it will form one of the brightest pages in the history of war, and will reflect honour not only upon those who have so nobly performed most dangerous duties, but on the profession to which they belong.

## M. VOILLEMIER.

OUR Paris correspondent writes: We have to deplore the loss of a distinguished *confrère* in the person of Dr. Voillemier, whose death has just taken place, at his residence in Paris, in the sixty-ninth year of his age. Dr. Voillemier was a very able surgeon; but it was with the diseases connected with the genito-urinary organs that he mostly distinguished himself. He was for a long time surgeon to the Hôtel Dieu, from which he had to retire on reaching the age limited for hospital surgeons—viz., sixty-four; being, however, allowed to retain the title of honorary surgeon. He took his degree in 1842, and was elected Member of the Academy of Medicine in 1873. He was raised to the dignity of Commander of the Legion of Honour for his distinguished services.

## THE FUNERAL OF CLAUDE BERNARD.

ALL that was mortal of the remains of Claude Bernard now reposes in the cemetery of Père la Chaise. His funeral took place on the 16th instant, at the expense of the State, in recognition of the great service he had rendered to science. The religious ceremony was performed at the church of St. Sulpice; and the body was accompanied to the grave by a great concourse of mourners, and with the military honours due to the deceased as Commander of the Legion of Honour. The *cortège* was a most imposing one; there were at least 3,000 persons, representing members of all classes and of both sexes. The pall was held by MM. Bardoux, the Minister of Public Instruction, Camille Doucet, Blanchard, Mézières, Laboulaye, and Fizeau, followed by medical students and by the representatives of the different learned bodies and members of the Chamber of Deputies and the Municipal Council of Paris. Five funeral discourses were pronounced over the grave: by M. Dumas, in the name of the Academy of Sciences; by M. Mézières, in the name of the French Academy; by M. Bouillaud, in the name of the Academy of Medicine; by M. Vulpian, in the name of the Faculty of Medicine; and by M. Laboulaye, in the name of the College of France. Marshal MacMahon was represented by an aide-de-camp at the funeral.

## THE SIGNIFICANCE OF THE CÆCUM.

DR. DUREAU (*Thèses de Paris*, 1877) discusses anew this subject by the light of comparative anatomy. The cæcum is rudimentary in man, carnivora, quadrumana, amphibia, insectivora, etc.; in rodents, pachyderms, and ruminants, it is of capital importance. Among birds, it is similarly reduced to a simple tubercle among the rapacious birds (essentially carnivorous), and is prodigiously developed among the gallinaceous and certain of the palmipeds. Among herbivorous animals and birds, it appears to serve as a reservoir of elaboration and absorption of the food, its removal leading to extreme emaciation. In man and other carnivores, it does not seem to be of any use. It exists, one might say, as an anatomical protest against vegetarianism.

## LARYNGOSTROBOSCOPY.

PROFESSOR OERTEL of Munich, in a preliminary communication to the *Centralblatt für die Medicinischen Wissenschaften* of February 2nd, announces that he has, by a method which he describes as the laryngostroboscopic investigation of the larynx, invented the means of showing the independent action of each of the vocal cords separately, and of distinguishing the velocities of their vibrations during the utterance of the notes of the chest and falsetto-register, inequalities in their vibrations, and various physiological and pathological conditions not previously accessible to observation. In the next number, he describes the method by which he retards the movements of the cords and observes them by powerful but intermittent artificial light, and simultaneously compares the movements of the cords with those of a revolving "stroboscopic" disc, or the vibrations of a tuning-fork set opposite to the mirror.

## SCOTLAND.

AT a meeting of the Fife and Kinross Lunacy Board, held last week, the resignation of the Superintendent of the Asylum, Dr. John Fraser, was accepted, as also that of his assistant Dr. Watson. Dr. Fraser has been appointed by Mr. Cross one of the Deputy Commissioners in Lunacy in Scotland. Dr. J. J. Brown, senior assistant at Morning-side, is the only candidate as yet spoken of for the vacancy.

THE Medical Officer of Health for Glasgow reports that, during the fortnight ending February 9th, there had been 594 deaths in the city, or at the annual rate of 27 per 1,000 living; 42 per cent. had been due to pulmonary diseases. There had been 12 deaths from fever, 11 of which were from typhus. One death had occurred from small-pox, that of a young gentleman, who had caught the disease in London.

SEVERAL stone coffins have recently been discovered near Dundee. They contained human bones, which were in a fairly good state of preservation. In one case, the bones were those of a man over six feet in height. The coffins are composed of rough slabs, measuring six feet and a half in length. The remains have been interred in the Eastern Necropolis, Dundee.

## HEALTH OF EDINBURGH.

IN his monthly report of the health of Edinburgh for January, the Medical Officer of Health shows that the death-rate was higher than usual; the number of deaths was 491, equal to an annual death-rate of 27.49 per 1,000. This high mortality was partly accounted for by additional deaths from measles and whooping cough, which amounted to 50. The city was reported to be otherwise healthy. No deaths had taken place from typhus fever, and there had been only three fatal cases of typhoid. Since February began, the deaths from measles have shown a weekly increase in numbers, having been 12 in the week ending February 2nd, 14 in that ending February 9th, and reaching the high total of 16 during the week ending on Saturday last.

## HEALTH OF ABERDEEN.

AT a meeting of the Aberdeen Town Council, last Monday, it was stated that there were three cases of small-pox in the Cunninghamhill Hospital, and that one death had taken place at Woodside from small-pox. All these cases had been traced to one and the same source, viz., the paper-mills at Stonewood. It was also mentioned that, since the January meeting of the Council, typhus fever had increased greatly and was still on the increase. During January, there had been 22 deaths in Aberdeen from zymotic diseases, eight of which had been the result of typhus and seven of scarlatina. One of the Council called attention to the report on the sanitary condition of Aberdeen, which had been read by Mr. Chadwick at the summer meeting of the Social

Science Congress in Aberdeen, but only published a short time ago. It stated that Mr. Chadwick considered the sanitary condition of Aberdeen superior to that of any other town in Scotland, and that he only remarked that something might yet be done to reduce the already small death-rate. It was agreed to remit to the Public Health Committee to consider as to the propriety of providing a Reception-house, in which members of poor families in crowded houses where infectious disease had appeared, and who had not as yet been attacked, might be temporarily accommodated until it was ascertained that the house was free from infection.

#### TYPHUS FEVER EPIDEMIC.

WE learn that the typhus fever epidemic is still unabated in Paisley, and has spread to other districts of the town besides the west-end. In the Infirmary, there were twenty-six cases; and, although several patients were discharged during the week cured, the rate of admissions is still very high. The fever is of a malignant type, and is proving exceedingly fatal among the patients being treated outside the Infirmary. The deaths in town for the week ending February 2nd were thirty-nine, against twenty in the corresponding week of 1877.

#### THE MILK-EPIDEMIC OF ENTERIC FEVER IN GLASGOW.

NOW that this epidemic is virtually at an end, Dr. Russell has reported to the Board the actual extent and fatality of it. In this report are only included cases which have actually been traced to infection by the suspected milk, and they amount to 163 in all. Of these, 72 were in Glasgow proper, 13 among students in the University, and 78 in neighbouring west-end suburbs. The death-rate was comparatively low, about 9.2 per cent., or 15 in all. It is noteworthy that the mortality among the students was very high, there being 3 deaths among 13 cases, or at the rate of 23 per cent. The Council passed a vote of thanks to Dr. Russell for his energy and care in tracing this epidemic.

#### CROWDING OF THE INFIRMARIES IN GLASGOW.

It is quite apparent that, even with the addition of the Western Infirmary, the hospital accommodation in Glasgow is still deficient in amount. A deputation, which waited on the Town Council on Monday, informed them that there were 80 patients waiting for admission to the Royal Infirmary and 60 to the Western, and they asked the Town Council to utilise their epidemic hospitals to accommodate some of this surplus. Such an arrangement can hardly be a satisfactory one, unless it be gone into on a permanent footing; and we suspect that the Council will hesitate before committing themselves to the treatment of general medical and surgical cases out of the public rates. The Western Infirmary has recently had a large sum of money left to add to its accommodation, and it would be a pity, in view of the apparently urgent need, that any delay should take place in beginning operations. We believe that the sum left will enable the infirmary to add nearly 200 beds, or about double its present accommodation.

### IRELAND.

TWO concerts will take place at Parsonstown on the 28th instant and 1st proximo, in aid of the funds of St. Mark's Ophthalmic Hospital, Dublin.

#### THE LATE DR. DONOVAN.

A PETITION has been presented to the Earl of Beaconsfield, praying him to grant a pension from the Civil List to the widow and unmarried daughters of the late Dr. Daniel Donovan, late medical officer of Skibbereen Workhouse and Dispensary, for whom he was unable to make any provision, in consequence of having suffered for eight years previously to his death from a disease which incapacitated him for work, and of the failure of the Albert Insurance Company, in which his life was largely insured. This appeal is more particularly founded upon the energy displayed by Dr. Donovan in grappling with the great Irish famine of 1846-47, which was more generally felt in Skibbereen than

elsewhere, and upon the value of the medical records of the famine made by Dr. Donovan during that period, which have been of great service in similar calamities of a like nature, and notably in the great famine in Madras. For these great services, Dr. Donovan received no reward.

#### ZYMOTIC DISEASES IN CORK.

DURING the past year, the deaths registered from measles amounted to 98 (96 of which were registered in the December quarter); diarrhoea, 74; fever, 66; diphtheria, 8; and scarlatina, 3. It is remarkable that there was not a death from whooping-cough registered during the year, whilst the mortality from scarlatina was extremely low.

#### BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

AT the annual meeting of this Branch recently held, the following office-bearers were elected for the ensuing year:—*Committee*: Drs. Cuming, Drennan, Ferguson, Filson, Gray, Harkin, Higginson, H. M. Johnston, McCleery, McClelland, McGee, James Moore, John Moore, Murney, Musgrave, C. D. Purdon, Ross, Brice Smith, J. T. N. Smith, Spedding, and Whitaker. *Honorary Secretary*: Dr. Wilberforce Arnold. *Honorary Treasurer*: Dr. Browne, J.P.

#### ZYMOTIC DISEASES IN BELFAST, 1877.

DURING the past year, but one death took place from small-pox; the deaths from the six other principal zymotic diseases being as follows:—Measles, 221 deaths; fever, 209; diarrhoea, 162; whooping-cough, 118; scarlet fever, 90; and diphtheria, 22. The total mortality from these causes was equal to 4.5 per 1,000 of the population, according to the census of 1871, or, allowing for the probable increase since that year, 4.0 per 1,000.

#### THE SAMARITAN HOSPITAL, BELFAST.

THE annual meeting of the friends of this useful institution was lately held in Belfast, the Chair being occupied by the President of the Queen's College. The hospital, which is intended for the treatment of diseases of women and children, is the only institution of its kind in the North of Ireland for the special objects for which it has been established. Since the last meeting, the hospital has been completely furnished, the wards now containing twenty-three beds; and an operating-room has been provided with a valuable collection of surgical instruments. Since the opening of the new building, three thousand two hundred and twenty-four persons have been treated in the extern department, and two hundred and forty-five patients have been relieved in the wards since the opening of the intern department. During the year, upwards of £400 were derived from paying patients. A vote of thanks to Drs. McMordie and Cuming, for their untiring zeal in promoting the objects of the hospital, terminated the proceedings.

#### THE LATE DR. PELLY.

A SPECIAL meeting of the Eyrecoort Dispensary Committee was held recently to express their regret at the death of their medical officer, Dr. Pelly, who lately died of fever. The following resolution was unanimously adopted:—"That this Committee do express the most profound regret at the death of their truly kind, attentive, and talented medical officer, Dr. Pelly. During the fifteen years Dr. Pelly attended the dispensary districts of Eyrecoort and Killimore, he discharged his duties to the sick and suffering poor faithfully and well. We deplore his death the more, as his fatal disease was caught in the fearless discharge of his professional duty. We tender to his afflicted widow and her helpless charge, also to his other relatives, our deepest sympathy in their irreparable loss."

#### ENNISCORTHY UNION.

AT a recent meeting of the Board of Guardians of this Union, a petition was received from the dispensary medical officers, calling the attention of the Board to the insufficiency of their present salaries, and soliciting a moderate increase. It appears that many years ago their salaries were

fixed at an uniform rate of £90 yearly; but since then the cost of every necessary of life has greatly increased, and in the neighbouring unions a corresponding increase has been given to the salaries of the dispensary medical officers. Notice has been given by one of the guardians that, on the 28th instant, he will move that all the salaries of the dispensary medical officers of the union be increased to £100 *per annum*; and we trust this instalment of justice will be obtained, as the medical officers of this union are the worst paid of any in the district.

#### CORK DISTRICT LUNATIC ASYLUM.

THE office of assistant to the medical superintendent of this asylum is now vacant by the promotion of Dr. Atkins. The appointment lies with the Board of Governors, who will select a successor on March 1st. Candidates must not be under 23, or above 35, unmarried, and are required to reside in the asylum. The salary is £110 *per annum*, with partly furnished house, coal, etc., and £50 in lieu of rations and attendance.

#### PHARMACEUTICAL SOCIETY OF IRELAND.

THIS society, which was incorporated by Act of Parliament on August 11th, 1875, has already on its register one hundred and fifty-eight pharmaceutical chemists and one hundred and one members. The first examination of candidates for the licence to act as pharmaceutical chemists was held on March 1st, 1876; and, from a statement recently published, we learn that sixty-nine candidates have passed their preliminary examination to come up for examination as pharmaceutical chemists under the new regulations at a future date. The Society may, therefore, be congratulated on their having shown in so short a time a very satisfactory *raison d'être*. Its financial position is also apparently established, since, although it commenced operations without any funds, it has now a balance to its credit of upwards of £300.

#### SCIENTIFIC LECTURES.

THE third lecture of this year's annual course of scientific lectures in the King and Queen's College of Physicians was delivered on Monday, February 18th, by Dr. Purser, King's Professor of the Institutes of Medicine in the University School of Physic. The subject chosen for this and the succeeding lecture was the anatomy and physiology of the white columns of the spinal cord. It was shown that, while anatomical examination of the fully developed cord gave little information as to the course of the fibres, the entire white matter appearing to form one whole, embryological investigation demonstrated that the white matter was highly complex, and consisted of seven distinct tracts which differed widely in the time of their first appearance and subsequent development. Four of these tracts were, for the most part, made up of fibres of the nerve-roots before they finally terminated in the grey matter, and of commissural fibres which connected portions of the grey substance lying at different levels. The tracts of this class varied in size in different regions of the cord, according to the amount of grey matter in, and the number of nerve-fibres entering or leaving, each part. The three remaining tracts were developed later, and differed from those of the first class in connecting the spinal cord with the brain. They increased steadily in size from below upwards. 1. The continuation of the anterior pyramids in the cord which, according to the amount of crossing of the fibres that occurs at the decussation, have a somewhat variable arrangement, connects the cerebrum (cortex and basal ganglia) with the grey matter of the spinal cord, the connection being probably, for the most part, with the cells of the anterior horn. 2. The direct lateral cerebellar tract, which lies at the periphery of the posterior part of the lateral column, effects a communication between the cells of Clarke's column and the cerebellum. 3. Goll's column, which appears to terminate alone in the post-pyramidal nucleus, has an uncertain spinal connection. The facts of human and experimental pathology were shown to confirm in a striking manner the results of embryological research.

#### SCIENTIFIC ENDOWMENTS FOR THE BRITISH MEDICAL ASSOCIATION.

THE following communication, giving particulars of his munificent proposition expressed in his letter published under the signature of "A Retired Surgeon" in the JOURNAL of December 15th, has been forwarded to the editor by Mr. Middlemore of Birmingham, and placed in the hands of the General Secretary, Mr. Fowke, for transmission to the Committee of Council. We feel sure that this generous offer will be warmly appreciated by that body, as well as by the Association at large. It will take its place by the side of, but separate from, the Stewart Prize Fund and the Hastings Memorial Fund.

"Richard Middlemore, F.R.C.S., Consulting Surgeon to the Birmingham Eye Hospital, is desirous of presenting to the Council of the British Medical Association the sum of five hundred pounds (£500) in trust for the following purpose.

"To found a prize to be awarded to the author of the best essay on the scientific and practical value of the improvements which have taken place in ophthalmic medicine and surgery during the previous three years.

"The prize to be adjudged every three years.

"If no essay of sufficient merit be sent in on any one occasion, then the award to be made the following year, and to be always so arranged that the triennial character of the prize shall be maintained, and that an unbroken series of records of the progress of ophthalmic science shall be preserved.

"Experience may demonstrate the necessity of altering the conditions of the trust. To provide for this contingency, Richard Middlemore would be happy to give power to the governing body of the British Medical Association to revise and vary the condition of the trust, while maintaining unaltered the object for which it is founded. Such revision to take place at periods of no less than ten (10) years.

"It is the donor's wish that the fund in question shall be kept separate and distinct from any other pecuniary gift which may be presented to the Council for a kindred object.—RICHARD MIDDLEMORE, Temple Row, Birmingham."

#### MEDICAL EDUCATION IN THE UNIVERSITY OF OXFORD.

A LETTER, of which the following is a translation, has been received from Professor Billroth of Vienna, in answer to one from an English *confère*, and has been handed to us for publication.

"Although I feel honoured by your inquiries respecting the advisability of extending the Medical Faculty in Oxford, and although I have given much attention to the subject, I hardly venture to express a decided opinion on the point. The development of our German Universities, their relation to the people and to practical life, is in so far different, that with us the *principle* of combining academical and practical instruction at the University is supreme. For myself, I am strongly on the side of those who allow no difference between the study of natural objects and natural laws on the one hand, and the study of the morbid human body on the other hand. In my view, there is only *one* method of investigating Nature and her laws; and this method is equally applicable to the analysis of a mineral, the examination of a plant, or the thorough investigation of the bodies of men and animals, whether in health or disease. The business of the clinical teacher is to teach this method at the bedside. Treatment is only the sum total, the ultimate conclusion attainable by us as the result of observation. For this study, the number of patients need not be excessively large. The largest number of beds which, in fact, can be applied to purposes of instruction, when two hours' clinical instruction are given daily, would be one hundred beds each for internal and external diseases respectively, and thirty for diseases of the eye; to which must be added the out-patients, whom I hold it important to use concurrently for purposes of instruction. It is possible, however, to give very successful teaching with a clinic of only fifty beds on each side; and most German Universities have clinics of only forty to sixty beds.

"There are diseases which can *only* be studied *rapidly* in large towns. To these belong the social diseases, such as syphilis, contagious skin-diseases, epidemics; also some rarer diseases, which are treated by special methods, such as diseases of the larynx, diseases of the ear, certain nervous diseases which are treated with electricity, etc. With us, most young doctors go for this purpose, when they have

finished their studies and passed their examinations, to Berlin, Vienna, Paris, or London.

"Two years ago, I wrote a book on the *Teaching and Learning of the Medical Sciences (Ueber das Lehren und Lernen der Medizinischen Wissenschaften)*, Gerold, Wien, 1876). You will find there all my views on those points in which you are interested.—I have the honour to be, etc.,

"DR. TH. BILLROTH.

"Vienna, January 31st, 1878."

### THE ARMY MEDICAL SERVICE.

MR. HARDY has, under stress of existing circumstances, been compelled to admit to the House of Commons that his scheme for popularising the Army Medical Department with the medical profession has broken down. This is exactly what the Parliamentary Committee of the British Medical Association plainly predicted to him at the moment of the inception of the plan; and they just as plainly pointed out to him the causes and the remedies of the unpopularity. Lord Herbert left the Army Medical Department flourishing, well organised, popular, and efficient; it has been the labour of each of Lord Herbert's successors to destroy his good work, and they have succeeded only too well; while Mr. Hardy only last year sneered at the alleged dissatisfaction of the Army Medical Department, and treated the whole question with a certain cynical contempt which was in itself hardly decorous, and certainly unlikely to contribute to the popularity of the department in the profession. The fact is, however, that there is no department of the public service more easily satisfied or more reasonably disposed; and, when Mr. Hardy sets himself seriously to promote the welfare of the department, he will find no difficulty in accomplishing his task, and he will find ourselves and the profession generally well disposed to meet him in the most cordial spirit, and to assist frankly and heartily in the satisfactory adjustment of the difficulties which have hitherto interfered with the efficiency of the department.

### THE YEAR 1877.

THE recent quarterly return of the Registrar-General states that "in the United Kingdom 1,153,398 births and 667,796 deaths were registered during the year 1877, equal to a birth-rate of 34.5, and a death-rate of 20.0 per 1000 persons estimated to be living in the middle of the year. The natural increase of population, by excess of births over deaths, was therefore 485,602, and 7,903 more than the excess in 1876. The actual increase is governed by the balance between immigration and emigration. No complete record of immigration exists, but returns issued by the Board of Trade show that, during 1877, emigrants of British origin to the number of 91,060 left the various ports of the United Kingdom at which emigration officers are stationed. Emigration continues to decline, and the number in 1877 was 11 per cent. lower than that in 1876, which showed a decline of 22 per cent. from the number in 1875. The decline in 1877 from the numbers in 1876 was equal to 11 per cent. in English, 14 per cent. in Scotch, and 12 per cent. in Irish emigrants. Of the 91,060 British emigrants during last year, 45,792 left for the United States, 29,703 for the Australian Colonies, 7,822 for British North America, and 7,743 for all other places.

"In England and Wales 887,055 births and 500,348 deaths were registered during 1877; the birth-rate was 36.1, and the death-rate 20.4 per 1000 persons living. The birth-rate exceeded by 0.5, while the death-rate was 1.6 below, the average rate in the ten preceding years. The death-rate was lower than that which has prevailed in any year since civil registration was established in 1837. The returns of marriages for the last three months of 1877 are not yet available; the marriage-rate in the first nine months of the year showed, however, a further decline from those which prevailed in the corresponding periods of recent years.

"English mortality may be said to have been stationary during the twenty years 1851-70. It is, however, satisfactory to find that during the first seven years of the current decade, the rate of mortality in England and Wales has showed a decided decline. During the ten years 1851-60, the average annual rate of mortality in England and Wales was equal to 22.2; and in the following ten years, 1861-70, to 25.5 per 1000; during the seven years 1871-7, the average annual rate declined to 21.6. This decline of 0.8 per 1000 in the death-rate during the past seven years, signifies that 132,433 persons have survived whose deaths would have been recorded had the death-rate been equal to that which prevailed during the twenty years 1851-70. There appears good

reason to infer that much of this saving of life, and consequent decrease of sickness, is both directly and indirectly due to the new era of sanitary progress inaugurated by the passing of the Public Health Acts of 1872 and 1875. It is only, however, necessary to point to the marked variations in local death-rates, and to the conclusive evidence of excessive mortality in the manufacturing and mining districts of Lancashire and Yorkshire, and elsewhere, to prove how much may be hoped from still further improvement in sanitary organisation and administration.

"The 500,348 deaths in 1877 included 120,611 of infants under one year of age, and 126,049 of persons aged upwards of 60 years. The rate of infant mortality measured by the proportion of deaths under one year to births registered, was equal to 136 per 1000, against 158 and 146 in 1875 and 1876. Infant mortality in 1877 was lower than in any year since 1837, when civil registration first supplied a satisfactory basis for its calculation. During 1876, and 1877, infant mortality averaged only 141 per 1000, whereas in the five preceding years it had been equal to 153 per 1000. The decline of infant mortality in 1877 was doubtless in some measure due to the moderate temperature during the summer, which caused an unusually low death-rate from infantile diarrhoea; but the decline was not confined to the summer quarter of the year, and therefore appears to afford evidence of improved sanitary condition. The rate of mortality among persons aged upwards of 60 years, was equal to 68.7 per 1,000 persons estimated to be living at those ages, which although almost identical with that which prevailed in 1876, showed a marked decline from the death-rates at similar ages in preceding years.

"The deaths registered in England and Wales during the year, from all causes, included 64,454 which were referred to the seven principal zymotic diseases, showing a further decline of 8,763 from the numbers referred to the same causes in 1875 and 1876. These 64,454 deaths included 4,280 from small-pox, 8,637 from measles, 14,230 from scarlet fever, 2,522 from diphtheria, 10,518 from whooping cough, 9,481 from fever, and 14,786 from diarrhoea. The death-rate from these seven diseases was equal to 2.6 per 1,000, against 3.3 and 3.0 in the two preceding years. The zymotic death-rate in 1877 appears to have been unprecedentedly low, and was no less than 1 per 1000 below the average zymotic rate in the seven years 1870-6; thus it may be estimated that about 24,547 lives survived the year 1877, that would have succumbed to these diseases had the rate equalled that which prevailed in the seven preceding years. The deaths referred to measles, scarlet fever, diphtheria, fever, and diarrhoea, were considerably less numerous than those in 1876, whereas the fatal cases of small-pox and whooping-cough showed an increase. During the seven years 1870-6, the annual death-rate from fever—including typhus, enteric, and simple fevers—showed a steady decline, which was fully maintained during 1877. The annual death-rate from fever, which was equal to 79 per 100,000 persons living in 1870, has since continuously declined, and during 1877 did not exceed 39 per 100,000, or less than half the rate that ruled in 1870. As the proportional mortality in cases of fever averages nearly 20 per cent., it may easily be calculated that the actual reduction of deaths from this disease only partly represents the gain to the community due to the steadily declining prevalence of fever.

"The inquest cases registered in 1877 were 25,623, equal to 5.1 per cent. of the total deaths; this was slightly below the proportion that prevailed in 1876. The deaths referred to different forms of violence were 16,718, and were 854 fewer than those resulting from violence in 1876."

## SPECIAL CORRESPONDENCE.

### PARIS.

[FROM OUR OWN CORRESPONDENT.]

*The Curse of Drink.—Iodide of Potassium in the Treatment of Asthma.—Tattooing the Cornea.—Pilocarpine as a Myotic.*

DR. LUNIER, a most indefatigable and zealous apostle of temperance, and one of the founders of the Temperance Society of France, has lately brought out a work on the production and consumption of alcoholic drinks in this country, and their influence on the physical and moral health of the populations. The volume under notice, which is the completion of a memoir read by Dr. Lunier before the Temperance Society of Paris in 1873, is, as indeed may be inferred from the title, a most interesting production—interesting alike to the vendors as it is to the consumers of wines and spirits; and even philanthropists, political economists, and the medical profession may derive most useful information from the work. From his official position as Inspector-General

of Lunatic Asylums and Prisons in France, Dr. Lunier has been enabled to consult documents from which he has obtained authentic information on the following points: 1. The proportion of offenders against the law prohibiting drunkenness in public; 2. The proportion of accidental deaths determined by excess of drinking; 3. The proportion of insanity caused by alcohol; the proportion of suicides attributed to alcoholism. On these divers questions, Dr. Lunier has arrived at conclusions which would make one shudder; and he has shown that the abuse of alcohol, whatever the form in which it is taken, will almost surely lead to crime, insanity, and suicide, if not to a lingering disease and eventual death. These, however, are only the immediate or direct consequences of the drunkard's evil habits; but when one contemplates the effects on the innocent victims that surround him, such as misery at home, brutal treatment of wife and children—the latter affected with idiotism, imbecility, convulsions, scrofula, pulmonary phthisis, and a host of other maladies, which are perpetuated even to the third and fourth generations—the picture is something awful, and no punishment can be severe enough for such offenders. Dr. Lunier, therefore, deserves the highest praise and gratitude of all right thinking men and women for his laudable efforts to put down the degrading vice; and if he had but a few more imitators, such scenes as are daily witnessed among drunkards and their families would be reduced to a minimum, society would benefit by the change, and the physical and moral condition of the people be improved in every way. To bring about these conditions, stringent laws and over-taxation of alcoholic beverages would be of no avail, unless, as Dr. Lunier observes, the populations received the benefit of elementary instruction and moral education, so that they might be able to read and learn for themselves the dangerous consequences of the abuse of alcoholic liquors. Dr. Lunier suggests other measures for the suppression of drunkenness, for which I must refer your readers to the work itself. I may, however, observe that, though teetotalism may be useful in its way, Dr. Lunier thinks it would be a waste of time to endeavour to introduce it into this or any other wine-growing country. In fact, Dr. Lunier is no enemy to wine-drinking in moderation; and he asserts that it has been proved, by long practical experience, that natural wine, that is, the unsophisticated juice of the grape after fermentation, is, of all alcoholic beverages, the best; it should not contain more than ten or eleven per cent. of alcohol. After this, comes beer; then cider; but, to be harmless, these also must be pure and natural. As for brandies and other spirituous liquors, he condemns them *in toto* as common beverages, though they may find their utility as therapeutic agents.

If Professor Germain Sée be not an original inventor or discoverer, he certainly deserves great credit as an innovator; for to him is due, in a great measure, the introduction into medical practice in this country of many old drugs and new remedies, which perhaps, but for him, would have been consigned to oblivion. I do not mean to insinuate by this that there are not in France other physicians of equal merit; but, whether from timidity or other cause, they are very slow in adopting any new discovery, unless it be *bona fide* French. For instance, I have only lately had occasion to speak of Professor Sée in connection with salicylic acid and its derivatives, which he popularised in this country, although, as he himself stated before the Academy of Medicine, these substances had been employed in Germany and Great Britain long before he brought them to special notice in France. At a recent meeting of the Academy of Medicine, M. Sée read a paper, in which he rehabilitates the efficacy of the iodide of potassium in the treatment of asthma. I say rehabilitates; because I find that, even on your side of the Channel, the remedy seems to be scarcely noticed, or almost forgotten, in the treatment of this affection. For nearly twenty years back, M. Sée has been employing the iodide of potassium for the cure of asthma; and, according to his experience, it may be looked on as a specific for the disease, if there be such a thing as a specific in medicine. It is true that others had employed it, and are still employing it, in this affection; but as it is invariably prescribed with other substances, such as ipecacuanha, opium, belladonna, ether, etc., it is difficult to say to which to attribute the curative effect. M. Sée has had the idea of trying the iodide of potassium alone, which has been followed with the happiest results. He prescribes it not only during the attack, but enjoins the patient to continue it for weeks, months, or years, according to the severity or duration of the malady. In exceptional cases, he combines it with a little opium, to prevent iodism, and, when the breathing is greatly oppressed, with chloral. During the paroxysm, however, M. Sée employs the iodide of ethyle, a substance discovered in 1825 by Gay-Lussac, and composed of iodine and ether, the new compound possessing the respective properties of both these substances. He administers it by inhalation, and he has often found that a single dose of five or six drops has been sufficient to cut short a paroxysm. The breathing once relieved, he then

trusts to the iodide of potassium to effect a cure. The above treatment has been found useful in all cases of asthma, whatever its origin; and the iodide of ethyle has also proved efficacious in relieving cardiac and laryngeal dyspnoea. For further information on the subject, I must refer your readers to this most interesting report, a full account of which will be found in the *Bulletin* of the Academy of Medicine.

Tattooing the cornea, for the purpose of masking the indelible cicatrices of leucoma, is becoming much in vogue among ophthalmologists in this country. The operation has certainly a great advantage in an æsthetic point of view; but, according to the experience of M. Panas, a distinguished surgeon and ophthalmologist, the operation is not so inoffensive as it is supposed to be, as he found, in a certain number of cases operated on by himself and others, that serious accidents have supervened in the form of irido-cyclitis, which he attributes to the presence of the colouring matter employed in tattooing, which, acting as a foreign body, sets up irritation and subsequent inflammation, as indicated by perikeratic injection, excessive lachrymation, and photophobia; but, when the operation is not followed by accident, M. Panas considers tattooing a great achievement in ophthalmic surgery, as he declared, at a recent meeting of the Société de Chirurgie, that it not only improves the outward appearance of the eye, but that in an optical point of view, and consequently more scientific, the sight is really improved in a notable manner. This fact should counterbalance every other consideration in the interest of the patient.

In connection with ophthalmic therapeutics, I may bring to notice a paper lately read by Dr. Galezewski, before the Biological Society of Paris, on the effects of pilocarpine, the active principle of jaborandi, on the eye. According to this well-known ophthalmologist, we possess in this new alkaloid a powerful myotic, equal in effect to that of eserine; but it has the great advantage over the latter in producing less irritation or other mischief in the eye; for he has noticed, after the use of eserine, that the patients have complained of intense ocular pains, followed by conjunctivitis attended with nausea. He employs pilocarpine in solution, selecting either the nitrate or the sulphate according to circumstances. In the former case, the strength of the solution is twenty centigrammes to ten grammes of distilled water; in the latter, ten centigrammes to six grammes. He prefers cherry laurel-water for the solution, as he has noticed that the pilocarpine loses its myotic properties after a time when it is made up with ordinary distilled water; and care must be taken that, whatever salt is employed, it must be perfectly neutral.

The death of M. Eugène Simmonet took place at Cannes, whither he had gone for the benefit of his health, in the sixty-third year of his age. M. Simmonet was a most enterprising medical publisher in Paris, and was very popular in the profession. He was the founder of the *France Médicale*, which, after being edited by Roubaud and other distinguished men, fell into the hands of Dr. Bontentuit, its present talented editor and proprietor.

## ASSOCIATION INTELLIGENCE.

### METROPOLITAN COUNTIES BRANCH.

AN ordinary meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesday, February 27th, at 8 P.M.; when Mr. T. HOLMES, F.R.C.S., will read a paper on Provident Dispensaries, to be followed by a discussion.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*  
W. CHAPMAN GRIGG, M.D. }

London, February 7th, 1878.

### STAFFORDSHIRE BRANCH.

THE second ordinary meeting of the Session will be held at the London and North Western Hotel, Stafford, on Thursday, February 28th, at 4.30 o'clock P.M. The Chair will be taken by Dr. Arlidge.

Members wishing to read papers or show specimens are earnestly requested to communicate at once with either of the Secretaries.

VINCENT JACKSON, } *Honorary Secretaries.*  
J. G. U. WEST, }

Wolverhampton, February 12th, 1878.

### LANCASHIRE AND CHESHIRE BRANCH.

THE first intermediate meeting of this Branch will be held at the Town Hall, Oldham, on Tuesday, March 5th, at 3.30 P.M.

Dr. W. H. Broadbent (London) has kindly consented to read a

paper on the Mechanism of Speech and Thought as illustrated by Pathology.

The following communications have also been promised.

Dr. G. J. Robertson will read the history of a case of Multiple Mammary Tumour.

Dr. Lloyd Roberts will exhibit some specimens of Distorted Pelvis.

Dr. Humphries will read a paper on Scarlatinal Nephritis, and show specimens illustrating its pathology.

Dr. Dreschfeld and Dr. Ross will exhibit, by means of the Oxyhydrogen light, Microscopic Sections illustrative of Disease of the Spinal Cord.

Mr. Jones will show a specimen of Necrosis of the Femur following Acute Suppurative Periostitis.

Dr. Leech and Mr. Cullingworth will show cases of Pseudo-hyper-trophic Paralysis.

Members wishing to read papers or to exhibit specimens, are requested to communicate with the Honorary Secretary as soon as possible.

Dinner will be provided at the Angel Hotel at 6 o'clock. Members intending to dine, are requested to send their names to Dr. G. Thomson, Oldham, on or before March 1st.

D. J. LEECH, M.D., *Honorary Secretary.*

96, Mosley Street, Manchester, February 13th, 1878.

#### NORTH WALES BRANCH.

THE intermediate meeting of this Branch will be held at the Owen Glyndwr Hotel, Corwen, Merionethshire, on Friday, March 8th, at 1 P.M.: R. ROBERTS, Esq., Portmadoc, President.

The Honorary Secretary will relate a case (with specimens) of Aneurism of the Ascending Aorta.

Members wishing to read papers or exhibit specimens are requested to communicate at once with the Honorary Secretary.

T. EYTON JONES, M.D., *Honorary Secretary.*

Wrexham, February 18th, 1878.

#### THAMES VALLEY BRANCH.

THE next meeting of the above Branch will take place at the Griffin Hotel, Kingston, on March 14th, at 5 o'clock.

Members who may be willing to read papers are requested to communicate with the Honorary Secretary as soon as possible.

There will be a dinner after the meeting (7 o'clock) at the above hotel. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Honorary Secretary.*

Kingston-on-Thames, February 12th, 1878.

#### BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE third ordinary meeting of this Branch was held at the Vork House, Bath, on Wednesday evening, January 30th. In the unavoidable absence of the President (Dr. MARSHALL), Dr. GOODRIDGE presided. There were present forty-one members.

*New Members.*—The following gentlemen were duly elected members of the Association and of the Branch: A. J. Harrison, M.B. (Clifton); J. G. Smith, Esq. (Bristol); Dudley Loftus Fitzgerald, M.D. (Tewton); Joseph Fuller, Esq. (Shirehampton); William Holman Lower, Esq. (Olveston); J. Ralph Guv, M.B. (Bristol); S. A. Holman, Esq., Deputy Inspector-General (Bath); and Dr. Gardner (Box).

*Discussion.*—The evening was devoted to a discussion on Hospitalism, which was introduced by Mr. R. W. TIBBETS, and led to an animated debate, in which Drs. Davey and Brabazon, Messrs. W. M. Clarke, Thompson, Crossman, R. S. Fowler, N. Crisp, and Dobson took part.—Mr. TIBBETS summed up in reply.

**LIVERPOOL MEDICAL MISSIONARY SOCIETY.**—This society held its fifteenth annual meeting in Hope Hall on January 21st. From the report read on that occasion, it appears that 21,190 new cases were entered at the two dispensaries conducted by the society during 1877; and the total of old and new cases together treated during the same period reached the large number of 89,087. In addition, the visits paid to the houses of the sick were 22,361; and the average daily attendance at the combined dispensaries was 347. Short religious services preceded the ordinary medical work each day; and various meetings of a more or less religious character were held in the dispensary premises during the week and on Sundays, which were numerously attended by the patients and their friends. The expenditure during the past year amounted to upwards of £1,700, and the present year commenced with a balance in hand of £9.

## CORRESPONDENCE.

### THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

SIR,—In reply to the questions pointedly put to me by Dr. Grigg, I may state (1) that I am responsible for the delay which occurred in the publication of the recent minutes of the Committee of Council, the delay arising from accidental circumstances. (2.) The selection from the minutes of the Committee of Council for publication has always been entrusted to the President of the Council; and, in discharging this duty, I have always been anxious to follow the practices of my predecessors. As to (3) the publication of a fuller report of the proceedings of the Committee of Council, I shall be ready to give such directions to the General Secretary as may meet with the approval of the Committee of Council.

Dr. Grigg is an *ex officio* member of the Committee of Council, and I trust he will not fail to submit the statements contained in his letter to the consideration of the Committee at its next meeting.—I am, sir, yours, etc.,

R. WILBRAHAM FALCONER, M.D., President of Council.

Bath, February 19th, 1878.

### THE LOST MEDICAL SCHOOL.

SIR,—Seeing that graduates of other universities are joining the ranks of those who desire the continued suppression of the Medical Faculty at Oxford, and being one of those who believe that its establishment there would be greatly to the advantage of the profession, of science, and of the University, I ask for space for a few remarks on the subject.

Doubtless, in occasional moments of self-complacency, the few Oxford graduates in medicine (there are now about sixty-six, of all ages, on the University books) may feel gratified at the pleasant things said of them by Dr. Ord and "M.D. Edin." in last week's JOURNAL; still more would they congratulate themselves did they quite realise their steady and quickening influence on their teachers and fellow-students in London. Granting, however, the fullest weight to these compliments, it yet remains for the question to be considered from an Oxford, not from a London, point of view. Is it the *raison d'être* of the Medical Faculty at Oxford to provide a scattering of good students to the London hospitals, or her highest function to supply leaven and salt to the medical schools? Oxford is, or rather should be, a great centre of learning and education in all branches; and one of the chief advantages of such centralisation of study is the mutual benefit gained by the intercourse of different minds working in different spheres of thought. Surely the good to be gained by the student of the vast and intricate subject of medicine, from opportunities of mental friction and wider general culture than could be obtained at one of the London schools, is no less to be prized than the reciprocal benefit reaped by other classes of students in the University from a larger admixture of the scientific and practical element, which is so useful an antidote to that superficial pedantry and priggishness occasionally attendant on purely literary studies. I am well assured that one who reveres the medical profession, and values the general Oxford training, would recognise a most happy result in their more frequent and intimate combination. This point, as well as many others that I would otherwise touch upon, is so admirably insisted on and clearly argued out by Dr. Michael Foster, in his recent pamphlet on *Medical Education at Cambridge*, that I will not venture to enlarge upon it. The pamphlet will recommend itself to all who love their Alma Mater and their profession. Dr. Foster shows satisfactorily that it is in the latter years of medical study, after the purely scientific course has been taken, and when the mind is engaged on clinical work, that widening influences should be brought to bear. This is the time when there is such imminent danger of a man settling down into a groove, and, studying medical diagnosis, for instance, as though it were as simple and definite as elementary practical chemistry, of becoming a narrow dogmatist, and, therefore, a bad physician. To no subject matter can the adage, "the proper study of mankind is man", be applied with such peculiar force as to that of clinical medicine. And the opportunities for such culture are plentiful in the social and intellectual intercourse of Oxford.

With all that is said of the excellence and value of biological teaching, as it exists at Oxford, most will agree; but the implication that Dr. Ord makes, when speaking of a "retrogressive policy", that scientific study would suffer by the establishment of the Medical Faculty at Oxford is perfectly gratuitous and against experience. The study of science for its own sake is very likely to flag when unallied with some practical element; however pure the idea, however high the aim, it is not consistent with human experience that research, especially in these modern days, will not suffer in the long run, if divorced altogether from some practical bearing. Notoriously, biological and chemical science have owed much to medicine. Dr. Michael Foster, who from a practitioner became a physiologist, says on this context: "Business is no less the nurse of science than science is the mother of business." And it is undeniable that biologists are likely to be in far the largest proportion attracted, as hitherto, from the ranks of medicine. Beginning to study physiology, as ancillary to medicine, many a man is allured by its interest to devote his life to it.

The practical arguments against the possibility of clinical instruction in Oxford, as Dr. Ord would probably admit, are "neither new nor original". They have been already stated and answered more than once; and, considering that good and sound clinical work, although of a voluntary nature, has occasionally been done by a student within the walls of the much depreciated Radcliffe Infirmary, and is being done in other hospitals as small and towns no larger than Oxford, perhaps call for no further comment. As Dr. Payne pointed out, in his letter to you in the early part of this controversy, the school, if properly established, will make this hospital all that is necessary for effective clinical teaching; and the attractions of Oxford, and fair emoluments, would inevitably ensure a staff of teachers worthy of the reputation of the University.

The point of the remarks of your correspondent "M.D. Edin." is somewhat hard to see. After complimenting the Oxford man as "the highest type of candidate for the special study of the medical art", all that can be said of him, when he has entered on that study, is that he "speedily reaches the level of, and in many instances surpasses, the rank and file of ordinary hospital pupils"! Is this a great feat for men of presumably far higher education, and with the start of from four to six years' seniority in age?

The failure of your Edinburgh correspondent to "imagine" Oxford teaching medicine is perhaps of not much argumentative importance; and the flattering consolation to her, for insignificance in number, of possessing the *corps d'élite* of the profession, is too vague to be of value, for it is scarcely in accordance with facts. Owing probably to the small total number of Oxford doctors, but very few attain to eminence; and the prizes of professional success are in the hands of still fewer. It would seem, too, that "M.D." was somewhat at a loss for an additional argument, when, to the statement that the professors at Oxford "had done splendid work and well maintained the character of their chairs", he appended a slight bathos as to "certain facilities offered to himself for study by one of them some years ago".

Lastly, the question seems obvious if, as Dr. Ord implies and "M.D." says, and some Oxford men think, the Oxford medical graduate is the salt of the profession, why not let us have some more of it? Why, instead, is there so much inconsistent opposition to any Oxford rivalry to London clinical teaching? Until there is a complete medical curriculum established at Oxford, so long will her graduates be few and far between. The long course of time alone required for medical graduation, under the present system, debars many from the mixed advantages of Oxford and medical training; and the great concurrent expense goes far to render the Oxford contingent to medicine a plutocracy rather than an aristocracy. But if, this good element in our midst, the Oxford medical man, were allowed to increase, doubtless many, if not most, would come to London to study for a time, even as those who enjoy the "unrivalled" opportunities of London may visit the Continent; and thus ample opportunity would offer itself to the London teacher for acknowledging their quickening influence.—I am, sir, yours faithfully,

HORATIO DONKIN, M.A., B.M.Oxon.,  
Senior Assistant-Physician to the Westminster  
Hospital.

London, February 12th, 1878.

SIR,—In discussing the question of the "Lost Medical School" at Oxford, there lies a fallacy which ought at once to be removed. It is objected that arts and medicine cannot be studied simultaneously; hence there is no use in their being taught in the same place. But surely this objection is vain. By the statutes of the University, no one can present himself at the first examination for the degree in Medicine until after the lapse of nearly two years, at least, after his acquisition of the degree of B.A., unless he has received very especial honour in the Final School of Natural Science. Now, to obtain this

special honour involves such a range and depth of study, that the provision practically nullifies itself; for the examinations in Natural Science are as searching and thorough as the teaching of its professors is sound and excellent. Consequently, in the natural course of things, the Oxford student of medicine of the future—who has a certain academic status at this day as "S.M." if he care to pay the extra fee for proceeding to this somewhat anomalous distinction—would first apply himself exclusively to the attainment of his degree in Arts; the subsequent study of medicine for two years at least in such an atmosphere of learning could not but be of infinite advantage. Only those who know what Oxford can offer to her graduates can fairly realise the value of such an intellectual life.—I am, sir, yours, etc.,

HENRY T. WHARTON, M.A.Oxon.

39, St. George's Road, Kilburn, N.W.

## THE ADMISSION OF WOMEN TO THE MEMBERSHIP OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—It will, I believe, be matter for great regret to the best friends of medical women, if any adequate cause have been given for reopening the question of the admission of ladies to the British Medical Association, in the ho-tile manner which the letters of your correspondents denote. The suggestions which more than one of them contain, as to what is creditable and characteristic of an English lady, prevent me from entering into any discussion with the writers; but I naturally feel called upon to reply to the arguments and plain suggestion in your temperate article on the subject.

In the first place, allow me to disclaim any share whatsoever in any action which may have called forth the present ill feeling, or any knowledge of it, beyond what I have gathered from the JOURNAL. The isolation in which I find myself placed, and the absence of common action between myself and the more prominent representatives of medical women, ought to relieve me from any responsibility they may have incurred. I certainly attended the annual meeting in Edinburgh, where I read a paper on a question of histological chemistry, so framed as not to shock even extraordinary susceptibilities. The antagonistic feeling manifested, and the results of the *publicité*, led me to absent myself from the subsequent meetings—a course I should probably have persisted in so long as my privileges as a member were not threatened, as I felt that, by so doing, I should best serve the interests of our cause, even at the expense of personal gratification.

Referring now to your article, I fail to see how any resolution come to by the Association can have any retrospective value in depriving any members of the rights and privileges which, in common with others, they acquired when they entered the Association, and which are still to be enjoyed by the rest of the members. If the privileges referred to could "in honour or equity", to use a phrase in the laws of the Association, be withdrawn, what really would remain of the privileges of membership, seeing that the JOURNAL may be bought for sixpence by anyone, irrespective of membership? The Association is only voluntary in the same sense as other societies are, that is to say, admission is voluntarily sought by the candidate, and as voluntarily accorded or refused by the Association.

I cannot admit that the result of the *publicité* was so startling as to call for resignation. Less than one-half of the members of the Association thought it worth while to give their opinion on the question; and of those that did vote, more than one-fourth were in favour of ladies entering the Association on the footing on which they now stand. If there is such a thing as the right of minorities, surely this is a case where it ought to be recognised. I think, moreover, that it is too much to expect that I should resign in deference to the prejudice of enemies, and in opposition to the opinion of 1,051 members; but, my respect for the latter is so great, that I am quite willing to leave my case in their hands. They cannot desire so strongly as I do that I should remain connected with the Association; nevertheless, if they consider, by a majority, that I ought to leave it, I will bow to their decision. In no society that I know of would a majority of less than three-fourths suffice to exclude a member, even for grave misconduct. If, therefore, three-fourths of the whole of the members of the Association vote, without further agitation, that the crime of being a medical woman warrants my being deprived of that membership to which I have already been admitted, and which I claim never to have forfeited, in that case also I will resign. I do not think that anyone could, consistently with self-respect, be willing to do more than I offer to do. I need hardly add that my decision binds no one but myself.—I remain, sir, your obedient servant,

FRANCES ELIZABETH HOGGAN, M.D., L.K.Q.C.P.I.

7, Trevor Terrace, Rutland Gate, S.W., February 15th, 1878.

## DENTISTS AND SURGEON-DENTISTS.

SIR,—In addition to the reasons given so forcibly in your leader of Saturday last, why dentists should be registered as dentists, and prevented from using in any way the title "surgeon" without having obtained a surgical diploma, another, and in my opinion a very strong one, remains to be urged on behalf of the public. In a communication I made to the *Lancet* in 1858, I advocated "the elevation of dental practitioners by a recognised qualification, and the consequent protection of the public from those who are unqualified; and that in future they be styled surgeon-dentists or dentists, according to their qualifications"—dental licentiates, dentists; and surgeons, being also dental licentiates, surgeon-dentists—the following passage being the basis of the latter suggestion. "At present, gentlemen practising dentistry style themselves at will surgeon-dentists or dentists, but the public generally do not regard the two designations as synonymous, and have the idea that a surgeon-dentist is a surgeon and also a dentist." That was true twenty years ago, and it is true now. The public, I know, still believe that a surgeon-dentist is a surgeon practising dentistry, and are surprised to learn that most so-called "surgeon-dentists" are only trained to the manufacture of artificial teeth.

There is now an opportunity such as cannot occur again of rescuing the honoured title of surgeon from use by thousands of dentists who have not the slightest right to it, and securing it in future to those who have earned the right; and I trust that your call to arms will be vigorously and universally responded to by the members of the Association.—Yours very truly, ALEXANDER STEWART, F.R.C.S.E.D.

112, Cheapside, February 19th, 1878.

P.S.—Your plan of placing "dentists" and "dental surgeons" on the same register, but in different columns, appears to meet the case effectively, and is so evidently just that members will have no difficulty in getting their representatives and any other members of Parliament they can influence to support it as an amendment.

## WEIGHT-EXTENSION IN DISEASE OF THE HIP.

SIR,—In his letter in the *JOURNAL* for February 9th, Mr. Adams somewhat misunderstands my objection to his original statement on this subject. If he will refer back to my first letter (January 26th), he will see that my object was not to contest the priority of an American surgeon in the use of the weight for the purpose of relieving pain, or for any other purpose, but merely to show that this practice, unquestionably useful as it is, is no *discovery*, whoever may have first adopted it. It is merely an obvious and almost a necessary development of Brodie's practice; and to claim any rights of discovery in a matter of this kind, whether for Dr. Davis or any one else, seems to me not merely to be an abuse of language, but also to foster the prevailing tendency to advance a "claim" to some so-called "discovery" or some special form of treatment or instrument, whereby the name of an individual can be connected with some common disease. I claim, as I said before, no priority or originality whatever for the use of the weight in hip-disease. At the Hospital for Sick Children, we certainly used it, as Mr. Adams says, for the relief of the pain so characteristic of the acute stage of the affection; and there is no doubt, as I stated in my former letter, that the stirrup of strapping by which it is fixed to the leg renders its use much more convenient than it was in Brodie's time; and this is an American invention, which I believed was due to Hancock. But I am quite unaware of anything in the history of weight-extension in this or any other affections of the joints which deserves to be ranked as a discovery.—Yours, etc., T. HOLMES.

London, February 1878.

SIR,—There can be no doubt whatever that Mr. Adams is quite wrong in supposing that the application of a weight to the foot, in the treatment of hip-joint disease, is a modern discovery. Mr. Holmes is perfectly correct in his remarks on this subject in the *JOURNAL* of January 26th. In the year 1860, I forwarded to the Royal Medical and Chirurgical Society a paper on the Treatment of Scrofulous Diseases of Bones, etc., which is endorsed by the Secretary: "Received November 3rd, 1860; read November 27th, 1860." It was read in abstract. In relating the particulars of a case of a boy, which I had under treatment in June 1856, the following paragraph occurs: "I placed the patient on an inclined plane, and fastened to his foot a pound weight, which worked through a pulley fixed to the bottom of the bed." "He bore the weight well, and I gradually increased it to four pounds." Some months back, soon after Mr. Adams's return from America, I mentioned this case to him, and stated there was certainly no novelty in the treatment; for that, about the same date, I well

remembered, a bone-setter at Manchester was tried for manslaughter, because a man had died, in the treatment of whose case (hip-disease) he had employed extension by means of a weight attached to the foot. I need scarcely make the remark that the man was acquitted. When Dr. Sayre was in London, I asked him to call upon me and I should be happy to show him the paper above alluded to, which, although much pressed for time, he kindly did; and in a very courteous manner acknowledged that the mode of treatment was not new, and strongly recommended me to preserve the paper as a valuable confirmation. From my house, Dr. Sayre and his son went with me to visit the children's wards connected with the Samaritan Hospital, where I had at that time five cases of hip-disease in different stages of treatment. After carefully examining them all, he expressed some surprise at not finding that any of them were treated by means of the extension-weight, and asked why I had discontinued its use. My answer was, because I could produce better results by other means, and that, as he had witnessed, my chief reliance was on "Thomas's splint". I may here observe that both Dr. Sayre and his son seemed well pleased, and made some very complimentary remarks. With regard to the treatment of these cases by a combination of motion and extension, I have always considered it not only a mistake, but in many cases most injurious, as long as any disease exists; and this opinion has been strongly confirmed by some cases I have seen lately. I consider Thomas's splint the best for all practical purposes, as, when pain is no longer present, it enables the patient to move about freely on crutches, a patten being fixed to the boot on the sound foot, so that the foot of the diseased limb cannot touch the ground, quite sufficient extension being thus kept up by the hanging of the limb itself. In this way, the general health is in no wise interfered with.—I am, yours, etc., A. WYNN WILLIAMS, M.D.

1, Montagu Square, W., January 28th, 1878.

SIR,—In the *JOURNAL* of January 26th, Mr. Holmes asks for evidence as to the value of the treatment of disease of the hip-joint by Sayre's splint. His experience has led him to believe that this treatment by extension, combined with motion, leads to unsatisfactory results. In this opinion, I can with confidence confirm him. I well remember that, five or six years ago, after a visit of Dr. Sayre to this country, the treatment of hip-disease had in Leeds a fair trial. The apparent benefit which attended the use of the splint at its first application led me, as well as others, to think that it would prove a great acquisition; but, unfortunately, we found that its application, instead of being beneficial, was decidedly the reverse. However carefully the instrument may be applied, the necessary extension soon relaxes, the bones come into apposition, fresh inflammation is induced, and the last state of the child is worse than the first. I can call to mind two cases in which this method of treatment was followed by excision of the joint, both of which would have, in all probability, been cured by rest and extension applied in the usual manner.

Shall we find that the newly introduced treatment of disease of the spine, which also aims at dispensing with rest in bed, is equally unsatisfactory? Time only can show; but some of the cases, in which I have lately used it, make me fear so. I can only hope that my fears will prove ungrounded.—I am, sir, yours, etc., A. F. MCGILL.

Park Square, Leeds, January 26th, 1878.

## CEREBRO-SPINAL FEVER.

SIR,—Within the last couple of months, there have been admitted into the Dundee Infirmary a number of cases of the above disease. A detailed account of the outbreak I hope to give on a future occasion. Meantime, I wish only to draw attention to its occurrence.

I do so because it may occur elsewhere than in Dundee; because, from its rarity and from its resemblance to other maladies, the real nature of the ailment may be very readily overlooked, especially in the homes of the poor; and because it is of importance that no opportunity should be lost of studying the natural history of a disease which is so comparatively rare, and of which we know so little.

As it exists here at present, it is undoubtedly contagious, affecting one member of a family after another; and bears, in many respects, so close a resemblance to typhus fever that it may very easily be mistaken for it. Indeed, most of our cases have been sent in as typhus.

The onset of the disease is characterised by rigors, sickness, intense headache, and often pains in the neck, trunk, and limbs. The headache continues; fever is marked; the breathing is specially quick and cerebral in character; the patient is restless, and has a look of great distress; the tongue is dry or furred; the bowels are confined; the urine is high coloured, deficient in chlorides, and sometimes contains a little albumen. There may or may not be an eruption on the skin. This,

when it occurs, more often resembles the typhus rash than any other. It is distinguished from that rash by its earlier appearance, its generally lighter colour, its more varying character, and its tendency to fade or change, rather than become more intense, as the malady advances. The cuticle, too, often desquamates freely in furfuraceous particles after cerebro-spinal fever.

The appearance of the patient is often very like that of a sufferer from typhus. Besides the above characters of the rash, the chief points by which cerebro-spinal fever may be distinguished from typhus are that, in the former, there is more often sickness at the onset; the headache is more intense; the breathing is apt to be cerebral from the commencement of the attack; the intellect is clearer, indeed often quite clear throughout the illness; there is less tendency to delirium and stupor; and the eyes are, as a rule, less suffused and injected.

The two maladies have often so close a general resemblance, that it must frequently be difficult, if not impossible, to make a satisfactory diagnosis in the badly lighted dwellings of many of the poor.

I hope that physicians practising in other localities will be on the outlook for what is always an interesting, and often a most alarming, disease. It is new to our hospital records.—Your obedient servant,

T. J. MACLAGAN, M.D.,

Physician to the Dundee Royal Infirmary; Examiner in Medicine to the University of Aberdeen.

### REFORMATION OF THE CORONER'S COURT.

SIR,—Relative to this subject, allow me to call attention to the necessity of selecting a more intelligent class of jurors. These are frequently chosen from the ignorant, illiterate, and idle ranks of society; their selection and appointment being dependent on the coroner, or on his officer through him. Ignorant or incompetent coroners are liable to the temptation of selecting ignorant and incompetent jurors, who, *addicti jurare in verba magistræ*, would never dream of doubting his findings, however foolish. Whether the deliberations of a coroner's court can be aided by the enlightened cogitations of such jurors, or whether any weight or value attach to their verdicts and censures, may be well doubted. Confidence is placed in inquiries conducted in public; but, since prisoners committed for trial on a coroner's warrant have their cases publicly investigated and judged by a jury a second time, it would seem that more publicity is allowed than seems necessary for the ends of justice. By a careful and searching preliminary investigation, or by a consultation in private, or by making use of evidence communicated to the coroner orally or in writing, not only might many unnecessary inquests be avoided, but the cause of death might be ascertained without invoking the assistance of twelve jurors, whose visit to the house of the deceased's friends to view the corpse must be anything but pleasant. The preliminary investigation ought to be made by a competent and qualified person, who should make a report to the coroner. Registrars of deaths might render service in this department, but unfortunately are unacquainted with the words expressing the causes of death which they register. The medical officer of health, in addition to being the "medical referee" or "pathologist assessor", might have a controlling power over the registration of deaths, he being the registrar-in-chief of a district or districts, and the present registrars might be related to him as clerks, or in some cases dispensed with. The registration of deaths would be more efficiently performed by medical men; but it is desirable that it should devolve upon a specialist, such as a medical officer of health, whose time ought not to be occupied by family practice.

Some one of your correspondents wisely remarked that a coroner ought to be "a man of sense". Coroners at inquests frequently avail themselves of this opportunity of talking about themselves and flourishing their supposed excellencies. Frequently these courts are the scene of a teetotal lecture; and I lately read of a coroner who, to the disgust of the public and to the torture of the feelings of the friends of the deceased, stated that the soul of the deceased was now in hell and in hell-fire; and the jury tamely acquiesced in this monstrous outrage. Coroners ought to be summarily called to account for such irrelevant disquisitions, and future legislation ought to limit their *libertas loquendi*.

The remedy to be adopted for the purpose of expunging and weeding out erratic and ignorant coroners, and retaining experienced and efficient members, is that, in future legislation on this subject, the following provisions should be made. 1. The area and amount of their work should be *redistributed*, and small districts should be enlarged in extent, and the amount of work increased. In this way, the number of coroners would be diminished. 2. Present coroners ought to devote themselves *entirely* to the duties of their office, and, if engaged in any other trade or profession, should be compelled to resign it, or resign their coroner-

ship. 3. If they retain their coronership and resign their profession, compensation ought to be made by increased remuneration. 4. Present coroners, who have held the office for a lengthened period and performed its duties in a satisfactory manner, should retire on a superannuation allowance.—I remain, etc.,

G. L.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### COUNTY BOARDS.

IT is not very often that we have the satisfaction of agreeing with Mr. Stansfeld in his legislative views. We see, however, with great satisfaction that Mr. Stansfeld has moved as an amendment, on the second reading of the County Government Bill, "That, with a view to simplify and strengthen local self-government, it is desirable, with as little delay as possible, to bring each sanitary district and Poor-law union within the area of one county, and to give to the ratepayers in and of such districts the power of directly electing members to the County Board exceeding in number the representatives of justices". This has so long been the object sought by the leading sanitarians in the country, as expressed in the reports of our Joint State Medicine Committee, that we are a little surprised that that Committee, which has so often urged the necessity of County Boards in connection with sanitary organisation, has not taken action in the matter. We also gently remind that Committee that very little result has yet been seen for the £100 grant which they received from the Association two years since, for a sanitary conference of medical officers and sanitary authorities.

### THE TREATMENT OF CASUALS IN GLOSSOP WORKHOUSE.

THE *Sheffield Independent* of the 13th instant gives a report of an inquest held at the Glossop Workhouse, Derbyshire, which merits some comment. It appeared that a professional tramp named Hall had walked from Hayfield to Glossop, accompanied by her three children, reaching the workhouse about 6 P.M. On her admission, she asked to see the doctor, as one of her children complained of being in great pain, and was, as was subsequently shown, very ill. The porter told her there was no doctor in the house; and she was shown, without food of any kind, into the casual ward; the only thing supplied her being some hot water, with which she made some tea from a small quantity she carried in her pocket. This she gave to her sick child. The ward contained no bed or bedding, only some raised boards and a rug with which the mother covered her child. She then, in company with another female and her two other children, lay down to sleep; the sick child continuing to moan and groan. About 9 P.M., the mother heard a rattling noise in the child's throat, and, on getting up to go to him, found that he was dead. The *post mortem* examination showed that the child (whose body gave evidence of being badly nourished) had died of inflammation of the bowels. The medical officer, Mr. Howard, further deposed that, if his attention had been called to the child when first admitted, he might have been relieved; that it was the duty of the master to communicate to him when any inmate or casual was taken ill; and that the mode of admission of casuals into the house was radically bad, for, on examination, he had found that one of the other children had measles; and that it was essential to any chance of life in the deceased that some food should have been given him when first admitted. We are not surprised to learn that, after such evidence, the correctness of which does not appear to have been impugned, the coroner should have commented in language of extreme severity. The whole story reveals a shocking indifference to human life and human suffering on the part of the resident officials; but they are not solely to blame. It is impossible to suppose that the mother and children would have been thus sent supperless to bed, in such a den, if it had not been in accordance with the orders of the board of guardians. We would also ask, Where was the inspector of the district, that he had failed to discover what were the rules and regulations in force in the Glossop casual wards? We perceive that Mr. Basil Cane (who, we presume, is the local inspector) has made an official inquiry. We hope that this will be moved for in the House, and that some question will be put which will elicit whether official inspection in the Derbyshire Poor-law District is or is not an useless but costly sham. A Local Government Board inquiry has been held on the question of the treatment of this woman and her children, but the results have not been reported.

## MILITARY AND NAVAL MEDICAL SERVICES.

### ARMY SURGEONS AND RIDING DRILL.

THE medical establishment at Aldershot has been largely increased by the arrival of twenty-four surgeons who have recently passed out of the Army Medical School at Netley. They have now entered upon a course of instruction in bearer company drill, and are also in regular attendance at the riding-school. This is the first time that riding drill has been ordered for medical officers on starting in the service. Hitherto, when army surgeons have attended military riding-schools—a rare occurrence, however—it has been at their own expense and as a voluntary undertaking. The importance of medical officers being able to ride well when on field-service, is greater than it might at first appear to be to those who have not had opportunities of observing the effects of incapacity in this regard. As pointed out in Professor Longmore's recent work on the treatment of gunshot injuries, familiarity with riding will be especially necessary for those medical officers who may be posted to bearer companies in the field. They must be mounted. This arises from the need that exists for them to keep up constantly with the troops of all arms, in order to be able to attend to men requiring their aid; from the frequency with which they will have to move to and fro rapidly while engaged in their special duties; and also in order that they may be spared all avoidable fatigue, so that they may be able to devote full energy to the important work which devolves on them, often at the close of the day, when other officers are free to obtain repose. There is good reason for hoping that the riding drill instruction which has just been initiated by the Director-General, Sir William Muir, will be continued in future with all young army medical officers on their first joining the service.

## MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, February 14th, 1878.

*Army Surgeons at the Cape.*—Dr. WARD asked the Secretary of State for War whether he had heard the reported dearth of army surgeons at the Cape; whether the report was correct; and in that case, whether he could explain how the emergency had arisen?—Mr. HARDY: Since the breaking out of hostilities at the Cape, two medical officers, whose term of service in that command had expired, were detained there, and six others have been sent from England, some of whom probably had not arrived when the letter referred to was written. Twenty-seven non-commissioned officers and men of the Army Hospital Corps have been despatched as an addition to the existing establishment, and a considerable supply of medical and surgical equipment has been forwarded. The military medical officers are sufficient for the number of troops; but private medical practitioners to the number of twelve are employed with the local volunteer force, and also at several of the base hospitals. The force is divided into so many small detachments, that it is impossible to supply military medical officers to all; but the important appointments and the movable field hospitals are in charge of military medical officers. With regard to the expense of the private medical practitioners, it is only temporary, and will cease with their temporary employment; and the rates of remuneration vary from 12s. to 40s. a day, only one being paid at the rate of three guineas a day. This expense is not greater than if military medical officers were employed, and is, as already stated, only temporary. The military authorities were lately referred to to know if any increase of medical officers or Army Hospital Corps had been asked for by the general officer commanding at the Cape; but the reply was in the negative.

Monday, February 18th.

*Her Majesty's Ship "Undaunted."*—In answer to Mr. Dodson, Mr. W. H. SMITH said that, since November 1877, there had been on board this vessel, now on the Bombay station, twenty-five cases of fever, of which one had proved fatal. The cases of continued fever were very simple, and easily yielded to treatment. During December, four men were sent home invalided, two from debility, and two from other causes. No officer had been invalided since August last. One case of small-pox was reported on the 27th of December. The number of officers invalided from the *Undaunted* had been considerably less than from the previous flagship during the same period.

*Army Medical Department.*—Dr. WARD asked the Secretary of State for War whether he would state what was the number of candidates for the recent examination for the Army Medical Department, and what was the number of vacancies advertised.—Mr. HARDY said there were

forty vacancies, and he regretted to say only nineteen candidates. That was a very unsatisfactory state of things, but he would make inquiries into the subject.

Tuesday, February 19th.

*Dental Practitioners' Bill.*—Sir J. LUBBOCK moved the second reading of the Bill, the object of which, he said, was to protect the public against quacks. The law very wisely provided that any person pretending to be a physician or surgeon, unless properly qualified, was rendered liable to a severe penalty. Chemists and druggists were not allowed to pursue their respective callings unless their qualifications had been tested by examination. It certainly seemed very anomalous that any person might call himself a dentist without the slightest qualification. Yet, the profession of a dentist was by no means simple or easy. The system proposed in the present Bill had been tried in America and in Canada, where it had worked very successfully. It was proposed to respect vested interests; nor, indeed, was it proposed to prevent anyone from pulling out teeth and acting otherwise as a dentist, but only to forbid him from using a title which would imply that he had special qualifications.—Dr. CAMERON moved the adjournment of the debate; and, after a short conversation, the House divided, and the numbers were: For the adjournment, 27; against it, 49; majority, 22.—Sir J. M'KENNA moved the adjournment of the House.—Mr. CROSS opposed the adjournment, which was supported by Dr. CAMERON and Mr. O'SULLIVAN. The House divided: For the adjournment, 11; against it, 61; majority, 50.—Mr. DILLWYN moved the adjournment of the debate.—Sir J. LUBBOCK said he should not further oppose; and the second reading was postponed until the 5th of March.

*Russian Prisoners.*—Sir J. M'KENNA asked the Under Secretary of State for Foreign Affairs if he could afford any information as to how the Russians disposed, and what has become, of Doctors Armand Leslie and Neville, who were made prisoners by the Russians at Kamarli early in January.—Mr. BOURKE: Drs. Armand Leslie, Neville, and Kirkpatrick were taken prisoners by the Russians at Kamarli and detained as prisoners of war for a month, until, on their arrival at Adrianople, the Grand Duke Nicholas, on the application of Consul Blunt, gave orders for their release. Lord Augustus Loftus was instructed to bring the facts as telegraphed by Mr. Layard before the Russian Government, and he was informed that the Commander-in-Chief regretted what had occurred, and had given orders for a rigorous inquiry, and for the severe punishment of the persons who had ill-treated the doctors. On their release, they proceeded to Constantinople, and Dr. Armand Leslie intended to return to England.\*

## OBITUARY.

CHARLES BLEECK, F.R.C.S., Warminster.

WITH regret we have to announce the death of Mr. Charles Bleeck of Warminster, an old and much esteemed member of the Association, which took place on February 4th. Mr. Bleeck was born in Warminster in 1805, and received his early professional education at the Bristol Royal Infirmary; he also studied for a short time at St. George's Hospital. He became a Licentiate of the Society of Apothecaries in 1827, and a Member of the Royal College of Surgeons in 1828; and soon afterwards commenced practice in his native town, where he remained until the end of his life. Soon after he had settled in Warminster, he was appointed a Poor-law medical officer under the old régime; he held the appointment seventeen years, and when he resigned it, had acquired a good share of private practice, which steadily increased until in time he gained the position of leading practitioner in the town and neighbourhood. In 1870, Mr. Bleeck was the President of the Bath and Bristol Branch; and two years later, was President of the Salisbury Medical Society. Both these honourable positions he filled with honour to himself and advantage to the Societies.

In his professional life, Mr. Bleeck won the esteem of all by his courteousness to his patients of all grades, his kindness to the poor, and his strictly honourable conduct towards other members of his profession. In private life, his hospitality was of the most generous kind. As a townsman, every work that was good or had the semblance of being made useful, obtained his active support; and this not only in Warminster, but sometimes at a distance, as in the case of the Bournemouth Convalescent Home, of the committee of which he was an active member.

A fortnight before his death, he had a very severe attack of gout, to which, it seems, he had been subject. Having rallied from this, he

\* The reporters in the daily papers have subjected Dr. Armand Leslie to a process of dichotomy—making him "Drs. Armand and Leslie".

endeavoured to accomplish an object which he had undertaken in connection with the meeting of the British Medical Association in Bath. Congestion of the lung appeared the following day; a few days later, embolism of the left femoral artery came on; and on February 4th, he died. His funeral was attended by a very large concourse of people from the town and neighbourhood for several miles around, who came to bear willing testimony to his worth and character. "His place knows him no more; but the memory of his useful, noble, and generous life will long be cherished in his native town."

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having undergone the necessary examinations, were admitted Licentiates in Dental Surgery at a meeting of the Board, on February 12th.

Alexander, Adolphus Benjamin, Hatton Garden.  
Clements, Thomas, Colville Road, W. (St. Mary's Hospital)  
Fort, James Wilson, Lancaster (Middlesex Hospital)  
Gurner, John Robert, Brussels  
Gillies, David, Londonderry  
Hardie, Walter Jackson, Montrose  
Rodway, Leonard, Torquay (Middlesex Hospital)

Two candidates having failed to acquit themselves to the satisfaction of the Board, were again referred to their studies.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, February 7th, 1878.

Davila, Pascoal Manoel, Tavistock Square, Bedford Square  
Gledhill, James, Peartree Street, Waterloo, S.E.  
Jeram, James William, Waterlooville, Hants  
Lendon, Alfred Austin, Maidstone, Kent

The following gentlemen also on the same day passed their primary professional examination.

Good, Frederick Thomas, St. Bartholomew's Hospital  
Williams, William, St. Thomas's Hospital

**ROYAL COLLEGE OF SURGEONS, EDINBURGH.**—The following gentlemen passed their first professional examination during the January examinations.

Robert Nelson Jack, County Tyrone; William Watt, Kirriemuir; Frederick Enos Fenton, London; Lindsey Barrett, Donegal; James Mulligan, Dro-more; and Charles A. Bestill, County Wicklow.

On the 1st instant, the following gentlemen passed their final examination and were admitted Licentiates of the College.

John Rankine, Stirling; Thomas Booth, Dublin; Edward Head Moore, Devonport; John Hay Caird, Fort George; Robert Davis Evans, North Wales; Herbert Lionel Reddy, Montreal; and Henry Mackintosh, Westport, Ireland.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH: DOUBLE QUALIFICATION.**—The following gentlemen passed their first professional examinations during the recent sittings of the examiners.

John George Brass, Barnard Castle; Thomas Harrop Roberts, Saddleworth; James Crofts Harris, Cork; John Scott, —; James Ross, Elgin; Henry Powell Williams, Liverpool; John Francis Grayling, Sittingbourne; Thomas Boymer Knight, Lincolnshire; James Hugh Robertson, Alnwick; John Joyner Fraser, Ross-shire; David Melville, Dundee; Isaac William Dalzell, Cumberland; Jones Hill Turner, Kingston-on-Thames; Robert Alexander Shannon, County Kildare; Alfred Emson, Dorchester; Thomas Wallace, Limerick; George Anthony O'Connor, Galway; and John Paxton, Norham.

The following gentlemen passed their final examination, and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh.

Walter Lorrain Rankine, Lanarkshire; Henry Ray, Australia; William Taylor M'Comb, Dublin; Samuel Arthur Stoddart Kennedy, Ayrshire; Hugh Williams, Anglesea; John Charles M'Lachlan, Yorkshire; William Ardagh Smyth, Trichinopoly, India; Isaiah George Butters, Devonport; Thomas William Drinkwater, Norwich; Richard Hamer Whiteley, Wakefield; Thomas M'Cormick, Castleberg; Julius Cesar, Cork; George Black Craig, Northumberland; James Bruce Macpherson, Londonderry; William Smyth Paterson, Passage West, Cork; William Alma Aylmer Lewis, Chester; Herbert St. Clare Carruthers, Southampton; Philip William George Canning, Jersey; Daniel Stenhouse, Auchterarder; Thomas Cassidy, Cape of Good Hope; Lewis Lloyd Pritchard, Northamptonshire; Alfred Edwin Lixey, Derbyshire; Lombard John Newman Tanner, Cork; and Thomas James M'Loughlin, County Meath.

## MEDICAL VACANCIES.

The following vacancies are announced:—

**BALROTHRY UNION.**—Medical Officer of Lusk Dispensary District. Salary, £125 a year as Medical Officer, and £20 10s. 8d. as Sanitary Officer, with the usual registration and vaccination fees. Election will take place on March 2nd.

**BROMYARD UNION.**—Parish of Cradley.—Medical Officer and Public Vaccinator. Salary, £50 per annum, and fees. Applications to be made on or before March 9th.

**FIFE and KINROSS LUNATIC ASYLUM.**—Medical Superintendent. Salary to commence at 350 per annum, with furnished house, coals, gas, vegetables, and washing. Applications to be made on or before the 25th instant.

**GENERAL INFIRMARY, Hertford.**—Medical Resident and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before March 6th.

**GENERAL INFIRMARY, Northampton.**—Surgeon. Salary, £250 per annum, with furnished apartments, board, attendance, and washing. Applications to be made on or before the 25th instant.

**GORT UNION.**—Medical Officer of Ardahan Dispensary District. Salary, £140 a year as Medical Officer, and £10 as Sanitary Officer, with Registration and Vaccination Fees. Election on March 14th.

**IPSWICH BOROUGH LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance.

**KENSINGTON DISPENSARY.**—Resident Medical Officer. Salary, £125 per annum, with furnished apartments, coals, gas, and attendance. Applications to be made on or before March 4th.

**KILLALA UNION.**—Medical Officer of Killala Dispensary District. Salary, £60 yearly, and £20 as Sanitary Officer. Applications to the 2nd inst.

**MILFORD UNION.**—Medical Officer of Kameelon Dispensary District. Salary, £115 yearly, exclusive of vaccination and registration fees; also £25 per annum as Medical Attendant of the Kameelon Fever Hospital. Applications up to the morning of the 25th instant.

**NARBERTH UNION.**—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.

**NATIONAL HOSPITAL FOR THE PARALYSED and EPILEPTIC, Bloomsbury.**—Resident Medical Officer and Registrar. Salary, £100 per annum, with board and residence. Applications to be made on or before the 25th instant.

**NORTHAMPTON GENERAL INFIRMARY.**—Junior House-Surgeon. Salary, £80 per annum, with board, furnished apartments, attendance, and washing. Applications to be made on or before the 25th instant.

**PORTMUNA UNION.**—Medical Officer of Eyrecourt and Killimere Dispensary Districts. Salary, £120 as Medical Officer, and £10 10s. as Sanitary Officer, with vaccination fees. Election will take place on March 1st.

**PUBLIC DISPENSARY, Stanhope Street, Clare Market.**—Resident Medical Officer. Salary, £105 per annum, with furnished apartments, coals, and gas. Applications to be made on or before March 4th.

**WESTMINSTER HOSPITAL.**—Aural Surgeon and Assistant Surgeon. Applications to be made on or before the 25th instant.

**WEST NORFOLK and LYNN HOSPITAL.**—House-Surgeon and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before March 1st.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

### DEATH.

\*PRICHARD, Thomas S., M.D., at Abington Abbey, Northampton, aged 53, on February 14th.

**THE HARVEY TRICENTENARY MEMORIAL FUND.**—A meeting of the London Executive Committee of this Fund was held yesterday (Thursday) at the Royal College of Physicians, at which Dr. Owen Rees (in the chair), Sir G. Burrows, Dr. Quain, Mr. John Simon, Mr. Prescott Hewett, and Mr. G. Eastes, one of the honorary secretaries, were present. It was resolved to prosecute the appeal for funds with all vigour, and measures were adopted for that purpose.

**ST. GEORGE'S HOSPITAL.**—Mr. Henry Lee, having recently resigned the post of Surgeon to St. George's Hospital, has been succeeded in that office by Mr. Pick, who was elected yesterday (Thursday) at a joint meeting of members of the lay committee and of the medical and surgical staffs of the Hospital, to which body all such questions of appointment are for the future to be submitted. At the same meeting, Mr. E. C. Stirling was elected Assistant-Surgeon in the vacancy created by Mr. Pick's promotion.

**CHARING CROSS HOSPITAL.**—The term of office of Mr. Canton and Mr. Hird as surgeons recently expired. Mr. Hird, who is also Dean of the Medical School, is re-appointed for a short term; and Mr. Bellamy succeeds Mr. Canton in the Surgeoncy. The election to the vacant post created by Mr. Bellamy's promotion will take place early next month. There are already various candidates for the office.

**THE WILL OF THE LATE DR. BLUNDELL.**—The will and codicil (dated April 11th, 1857, and March 17th, 1876) of Dr. James Blundell, formerly of 1, Great George Street, Westminster, but late of 80, Piccadilly, who died on the 15th ult., was proved on the 29th ult., by George Augustus Frederick Wilks, M.D., the nephew, and Samuel Frederick Noyes, the surviving executors, the personal estate being sworn under £550,000. The testator leaves to his sister, Miss Mary Blundell, an annuity of £800, and all his furniture, plate, pictures, household effects, horses, and carriages; to his half-sister, Miss Ann Blundell, an annuity of £250; to his nephew Bezer Blundell, £14,000 Consols; to his nephew Dr. Wilks, all his freehold, copyhold, and leasehold estates, and £35,000 Reduced Bank Annuities; to the London Hospital, £500; to St. Mary's Hospital, Paddington, £250; and there are other legacies and annuities to relatives, friends, and servants. The residue of his personalty is given upon trust for his niece, Mrs. Sarah Haighton Noyes, and her children.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.
TUESDAY.....	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY..	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.
THURSDAY....	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.
FRIDAY .....	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
SATURDAY....	St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY.—Medical Society of London, 8.30 P.M. Dr. J. Milner Fothergill, "Case of Opium Poisoning treated by the Hypodermic Injection of Solution of Sulphate of Atropia"; Dr. Day (of Stafford), "Observations and Comments on Certain Convulsive Disorders".
- TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Broadbent, "On a Case of Amnesia"; Mr. Brodhurst, "On a Case of Ankylosis of both Knee-joints, with shortening of the Femora"; Dr. Dickinson's Microscopic Preparations illustrating the Pathology of Diabetes will be arranged for inspection by 3 P.M.
- WEDNESDAY.—Hunterian Society, 7.30 P.M.: Council Meeting, 8 P.M.: Mr. R. Clément Lucas, "On the Treatment of Lupus by Erasion".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

- CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.
- CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.
- AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.
- PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.
- COMMUNICATIONS respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

THE following communications have been handed to the General Manager:—Mr. E. Roberts, Wrexham; Mr. J. F. Watson, Norwich; Mr. J. Cuckson, Birmingham; Messrs. Probyn, London; Dr. C. C. Gibbes, Salisbury; Dr. J. W. Moore, Dublin; Dr. E. T. Tibbits, Bradford.

## HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN SQUARE.

SIR,—In the report of the annual meeting of this institution, which appears in a medical paper of February 14th, the following startling announcement is made:—  
"After the Report had been read, the secretary read a requisition purporting to be signed by twenty-one subscribers, amongst whom were several of the nobility, requiring the committee to call a meeting to consider the circumstances connected with the so-called Committee of Inquiry." Lord Calthorpe then stated that he had seen Lord Rosebery in the House of Lords on Friday, and he had stated that he had never signed any document of the kind, and he could not understand how his signature had been appended to the document in question. Lord Calthorpe further stated that he had seen Sir Charles Legard, who, on being asked whether he had signed the requisition, said that he had received a memorial with a letter from Colonel Pelling, and that he had signed it, but he did not know what it had reference to. A subscriber suggested that after the observations of the President, it would be necessary to make inquiries as to the genuineness of the other signatures.  
In plain English, a charge of forgery is preferred against some person or persons. I therefore beg to inform that section of the public who take an interest in the above-named institution, through your columns, that Lord Rosebery did sign the requisition, and further, that Sir Charles Legard perfectly understands the purport of the requisition to which he appended his signature, having spoken to him on the subject myself.

Hoping that this letter may serve to quiet the mind of the subscriber who "suggested that after the observations of the President it would be necessary to make inquiries as to the genuineness of the other signatures", I remain, yours faithfully,  
Brook Street, February 20th, 1878. DUNMORE.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

ADVERTISERS are requested to take notice that the regulations of the *Post Office* do not allow letters to be addressed to initials and directed to any *Post Office* in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a *Post Office*.

## JUDICIAL POST MORTEM EXAMINATIONS IN SCOTLAND.

SIR,—Allow me to correct a mistake you have fallen into in your note appended to my letter in your *JOURNAL* of Saturday last. You imply that the Fiscal did not know that I had seen the body of the deceased, and had made arrangements with the widow to inspect it; but if you will refer to the Fiscal's first letter to me, you will see that at the time he applied for a remit to Dr. Ogston he was aware of both these facts.

As you seem to think that I have put my complaint on too narrow grounds, I may now say that if this had been a solitary case of want of "equity and courtesy" on the part of the Fiscal, "you would have heard nothing of it". That it is not so, is proved by Mr. Cadenhead himself in his circular to the profession here in 1876, in which he states that he had received a statement "formally in writing, to the effect that the medical profession entertains a strong belief, and feels keenly, that in the matter of judicial reprints and employments I fail to treat them with that equity and courtesy which the crown intends they should be treated with". To illustrate how this feeling has arisen, I shall briefly narrate, as examples, the two cases which called forth the circular I have just now quoted from. In October 1876, Dr. Jackson, a gentleman who deservedly occupies a foremost position in the profession in Aberdeen, reported to the Fiscal a case of sudden death to which he had been called. Dr. Jackson, whose qualification dates back to 1849, was not named in the remit; but Dr. Frank Ogston, who is the Fiscal's nephew, who occupies no official position whatever, and whose qualification dates only to 1873, carried out the remit. In November 1876, Dr. Jackson again reported a case of supposed infanticide. In this case, also, he was not named in the remit; but Dr. Frank Ogston was again employed in carrying the remit out. I could tell of several similar cases in which other medical men have been treated in a similar fashion; but I think I have said enough to show that there is good ground for the discontent which prevails here about the conduct of the Fiscal in such cases.

I hope you will find room for my queries to Dr. Littlejohn and his replies, as they show how marked the contrast is between the way such matters are managed here and in Edinburgh.

I see an article in your contemporary the *Medical Times and Gazette* on this correspondence. How far this is likely to be impartial, may be judged by the fact that Dr. Frank Ogston was circulating a printed copy of the article here on Friday, before the *Gazette* was published.—I am, yours truly,

Aberdeen, Feb. 18th, 1878.

ANGUS FRASER, M.D.

WE are requested to call attention to the fact, that the letter recently published from Leeds, in support of Dr. Drysdale and Mrs. Besant, was from the pen of Mr. Henry Arthur Allbutt, and not from that of Dr. Clifford Allbutt, to whom it has been by some persons quite erroneously and carelessly attributed.

## MEDICAL ETIQUETTE.

SIR,—Since Mr. Box's last letter, which cannot be considered an answer to mine of the preceding week, I have consulted many of my friends, and they are unanimously of opinion that the serious charges brought against me—in effect, those of "malice, malpractice, and untruthfulness"—ought to be substantiated by some direct evidence on the part of Mr. Box. Reiteration, negative evidence, and the asking of one question in answer to another, should be inadmissible in support of such serious charges. Mr. Box has been twice before challenged, without effect, to substantiate his charges on my "imagination", to prove that the ulna was not broken, and that the gentlemen in Shrewsbury were of the "unanimous opinion" he states. Till he attempt to do so, I decline to take further notice of him; and as my defence will consist of the *written* evidence of twelve witnesses, it would be folly to trouble you with so lengthy a document in the present state of the case. Mr. Box's statement about the colliery managers reminds me that the man Morris first came to the hospital with a letter purporting to come from the managers of the colliery in question, with a printed heading, and signed by one of their employers, asking that his case should be attended to. The lady-superintendent sent him to me, as surgeon of the week; and, as the managers are subscribers, I sent him in. I was not aware, nor can I find it in the rules, that arm-cases are not admitted, nor did it come to my knowledge for some weeks that the man was a pauper. As the certificate intended for the colliery has, I am told, been exhibited to the general public, it is only fair the profession should now see it.—I am, yours, etc.,  
February 1878. W. D. BRESFORD.

## BICARBONATE OF SODA IN BURNS.

CASE I.—On the 2nd of December last, I saw G., aged 18. He was standing in the centre of the room in a state of intense agony. His whole body, from the waist upwards, had been scalded by the overturning of a pot of boiling water. Having seen an account of the soda treatment a short time before, I was induced to give it a trial. Not being able to obtain anything else at the time, I made a strong solution of the ordinary "bread-soda" in warm water: this I applied freely. The relief experienced was immediate, and cure complete in a fortnight.

CASE II.—A short time afterwards, a child in the same neighbourhood fell face forwards on the fire, and a woman who was present when I applied the soda in the first case, made a solution and applied it in the same way, with results equally satisfactory.

CASE III.—A child two years of age had been badly burned by falling on the fire. The whole front of the child's chest was quite skinned and raw. In this case also the soda solution acted well. All these cases were of a grave nature. The first was so serious that I almost despaired of recovery; yet under the soda-solution they all recovered, without any bad symptoms.

Whitwick, February 16th, 1878.

WILLIAM DONOVAN.

## POISONOUS DISINFECTANTS.

AT the Liverpool Coroner's Court, Mr. Clarke Aspinall held an inquest a short time ago upon the body of Elizabeth Lavell, forty-two years of age, wife of a stevedore. The deceased, who was said to be addicted to drunkenness, and to have been in liquor at the time, drank some carbolic acid from a cup, saying, "Now I have done it," and died from the effects of the poison next morning. A verdict to the effect that the deceased had committed suicide while labouring under temporary insanity was returned.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### COMPOSITION AND QUALITY OF THE METROPOLITAN WATER IN JANUARY 1878.

The following are the returns made by Dr. C. Meymott Tidy to the Society of Medical Officers of Health.

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen used to Oxidise Organic Matter.	Nitrogen As Nitrates, &c.	Ammonia.		Hardness. (Clarke's Scale.)	
				Saline.	Organic.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains.	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction ..	20.40	0.114	0.090	0.000	0.003	13.2	3.7
West Middlesex ..	21.20	0.142	0.126	0.000	0.003	14.3	3.7
Southwark and Vauxhall ..	21.40	0.060	0.126	0.002	0.009	13.7	3.7
Chelsea ..	21.40	0.053	0.150	0.002	0.009	14.5	3.7
Lambeth ..	21.40	0.073	0.152	0.002	0.007	14.3	3.7
<i>Other Companies.</i>							
Kent ..	27.40	0.009	0.345	0.001	0.004	18.2	5.5
New River ..	21.90	0.025	0.135	0.001	0.003	15.4	2.3
East London ..	20.90	0.027	0.060	0.000	0.000	12.6	4.2

*Note.*—The amount of oxygen required to oxidise the organic matter, nitrates, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters, the quantity of organic matter is about eight times the amount of oxygen required by it. The water was found to be clear and nearly colourless in all cases but the following, when it was slightly turbid—namely, in that of the Southwark and Vauxhall, and the Lambeth Companies.

#### REMOVAL OF FOREIGN BODIES FROM THE AUDITORY CANAL.

SIR,—The ingenious mode of removing foreign bodies from the external auditory meatus, adopted in a case by Dr. Gray, and by him reported in the JOURNAL of February 9th, is the invention of Loewenberg of Paris. He described this method in either the *Monatschrift or Arch. für Ohrenheilk.* about 1870-71. Certainly, on a visit to Paris in 1872, my friend showed to me several examples of foreign bodies removed by this method. Also, in this JOURNAL on the 26th December, 1874, I described the "agglutinate" method of Loewenberg in my paper on the Removal of Foreign Bodies from the Ear.—I am, etc.,

JAS. PATTERSON CASSELLS, M.D., Aural Surgeon  
Glasgow Royal Infirmary.

February 1878.

#### VACCINATION DIRECT FROM THE CALF.

SIR,—Vaccine-lymph, as used in the days of Jenner, being in close relationship to its original source, the heifer was believed by him to afford a perfect protection against small-pox. This lymph has not been generally renewed for eighty years, and in consequence has gradually deteriorated in quality, as is proved by its comparative inefficiency at the present day, as witnessed by the ever recurring epidemics of small-pox. That vaccine-lymph derived from human beings may communicate syphilis, all now admit; and that serious and even fatal erysipelas may also arise from its use, is also admitted. Lymph derived from the bovine race is entirely free from these objections. It cannot possibly convey syphilis; and it has never, when properly obtained and used, been known to cause erysipelas. Moreover, its efficiency is so complete, that no instance has been recorded of any individual so vaccinated having ever taken small-pox afterwards.

Vaccination direct from the calf has been the national system in Belgium during the last ten years, while one million supplies of bovine-lymph have been disposed of by Dr. Henry Martin of Boston, United States, during the last six years. These facts speak for themselves. The success with calf-lymph is about 99 per cent. in cases of primary vaccinations, and our success has been about 75 per cent. in secondary vaccinations. We have successfully vaccinated calves during the last eleven months with pure lymph derived from other calves, and never from small-pox, as some ignorantly suppose: and having visited Belgium, and with Dr. Warlomont's most courteous assistance, made ourselves intimately acquainted with the minute details of the process, we are prepared to guarantee the profession a continuous supply of fresh calf-lymph on points and tubes as advertised.

We have opened an office at 264, Oxford Street, and we invite the medical men to visit us there daily, except Saturday, from two to three o'clock, at which hour cases may be inspected. We would also remind medical men that the anti-vaccination movement is daily gaining strength, and that its only argument—the danger of erysipelas and syphilis—is at once answered by the use of calf-lymph.

We recommend a few punctures or scratches to be made, when the point, being moistened, is rubbed over these marks, the skin being slightly stretched.—We are, etc.,

GEORGE WYLD, M.D. Edin.  
THOMAS WILSON, L.R.C.P. Edin.

February 5th, 1878.

JOHN C. O. (Hanson, Durham).—No; only to the ordinary fee for *post mortem* examination.

#### DR. SOUTHEY'S TROCAR AND CANNULE.

SIR,—This small waistcoat-pocket instrument consists of a minute trocar with four silver cannule, which are inserted into dropsical limbs and left to drain off the serous fluid. They may be left for a length of time without danger or discomfort; and I have been much struck with the large amount of fluid which in a single night will be drained off—in some cases, half a gallon. The instrument, which has been well made by Mr. Hawksley of Oxford Street, will serve the purpose of an exploring trocar; and in a case which I recently saw in Lancashire with Mr. Frederick Nash of Todmorden, that gentleman used it for this purpose in the first instance, where the tumour was abdominal and of doubtful character.

It is impossible to speak too highly of this useful and portable trocar, which every practitioner would find a safe and valuable acquisition.—I am, sir, your obedient servant,

R. G. ALEXANDER, B.A., M.B., Physician to the  
Bradford General Infirmary

February 1878.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### TRANSIENT TUMOURS.

SIR,—At present I have under observation the following case. A male child, seventeen months old, well developed, robust, and "usually healthy," is subject, at intervals of a few months, to swellings on different parts of the body; the only exceptions, seemingly, being the front of the thorax and abdomen. It is first noticed that the child is "out of sorts," has no appetite, but without any decidedly severe symptoms. About four days after this, there appears, perhaps on the arm, tumour, which is accompanied by pain. It increases in size up to the fourth day or so, when it disappears at the same rate, giving place to ecchymosis; and if seen at this period, leads the observer to believe the patient has been bruised. The swelling is of a hard consistence throughout, not freely movable nor well defined, but shading off to adjacent parts, the skin pale and shining, but no pain or tenderness on pressure. The appearance of a small patch of discoloration is the first indication of the decline of the tumour, and it in turn increases in extent until the fourth day, when it passes off in the same order. This is the fourth generation in which it has appeared; it has attacked all the male members of the family, and never the female, and has in every instance hitherto proved fatal in the course of time. There is one fact which may point to the pathology of the lesion—namely, that all the persons so affected have been liable to copious hæmorrhage, even from a mere abrasion of the skin. Have you or any of your readers experience of this disease? If so, can you refer me to any remedies beyond iodide of potassium, iron, and general tonic treatment, which, so far, have had no effect?—I am, sir, yours, etc., M. B.

\* \* \* From our correspondent's description, the tumours appear to be ecchymoses, indicating—in conjunction with the liability to bleeding which he mentions—the existence of the hæmorrhagic diathesis.

#### THE TREATMENT OF HYDROPHOBIA.

SIR,—I have lately had two cases which appear to me to bear on the subject of the treatment of hydrophobia. Considering that this dreadful disease is uniformly fatal in England, I am at a loss to understand how it is that such a powerful eliminator of animal poisons as mercury should be so much neglected. The first case was that of a medical friend, who inoculated his system with syphilis when operating for phimos. Mercury, given in the usual small doses and in a great variety of form, did not arrest the disease, the secondary eruption steadily increasing. At last calomel, given in five grain doses, acted like a charm, and the patient is now well. It was given at sufficient intervals, so as to stop short of producing more than slight salivation.

The other case was a poisoned wound of the hand, caused by the edge of a preserved meat-tin. Like the case of syphilis, there was a latent period, and the dangerous symptoms did not come on until about a fortnight or three weeks after the injury—the wound keeping open, and being much indurated at the edges. Finally, there was great constitutional disturbance, with rigors, severe cough, pain in the chest, etc.; and the case looked very serious. The lymphatics of the arm became inflamed, and a small abscess formed over the root of the thumb. Calomel and James's powder were given with the most marked relief, and the man quickly recovered. The calomel produced severe purging.

Many years ago, I tried to save a pointer dog which was suffering from hydrophobia; and, noticing that the power of swallowing both solids and liquids was quite lost after the first day, I gave several injections of beef-tea by the rectum. The treatment, however, was too dangerous, and I gave it up; but after each injection the dog was quite lively, and I became sanguine about his recovery.

To supply water to the blood and to rapidly eliminate the poison are doubtless the indications for treatment, and the calomel vapour-bath may supply them. Why is this course of treatment, which has already proved successful in India, neglected in England? Will not some of your readers give it a trial?—I am, sir, your obedient servant,

A. M. D.

#### HOW TO STOP A JOURNAL GRACEFULLY.

THE *Louisville Medical News* writes:—"There are several formulas for stopping a journal gracefully—all built, however, upon the foundation of 'closed please find x dollars and y cents.' We append examples. "Editor's News: Please find inclosed x dollars and y cents in payment of my account to date. Having unfortunately been deprived of my sight and hearing at the same time, so that I can neither read nor be read to, I am forced to request the discontinuance of your admirable journal. Trusting that it may continue uninterrupted on its course to the stars, and that your path may be strewn with life's choicest holly-hocks, I bid my way to subscribe myself, ever devotedly and gratefully yours, SMITH." And again, "Editor's News: Inclosed, etc. As executor of Dr. Brown's estate, I am directed to settle his account with your journal, and to direct its discontinuance. I was instructed also by Dr. B. to convey to you his apologies and regrets at this action on my part, and to assure you that but for the accident of his death nothing would have been further from his mind than quitting the *News*, without which life would have been a burden. JONES."—Such assurances of regard are very grateful to our feelings, and do much toward assuaging our grief at the reception of such letters as these, of which we have also had a modicum. "Editor's News: Your dun (a modest bill) for two years' subscription to the *News* has been received. Stop sending me the journal, as I am not to be insulted in this manner. (No inclosure.) A. B. C." "Post Office Official: The *L. M. News*, to the address of N. Y., or Z. Z., remains dead in this office. Reason—N. Y., or Z. Z. is dead-beat, removed, or does it want it. So-and-so, Postmaster."—But how much better than all these is to open the letter saying, "Keep on with the *News*, and good luck to you!"

#### SURGICAL SUPERSTITION.

IN his wonderful escape from the castle of St. Angelo, Benvenuto Cellini, besides receiving other injuries, broke his leg about three inches above the ankle. He was ultimately received into the house of the Cardinal Camerario, who had him attended by the chief physicians of Rome. "Among these was Master Jacopo da Perugia, a very excellent surgeon. He set my leg, and bound my arm (to raise the vein), and with his own hands took blood; but, on account of the vein being more swollen than ordinary, and further because he had made a larger incision than usual, occasioned the blood to issue with great force, so that it flew over his face, and he was covered with such profusion, that he could hardly be prevailed on to take further charge of me. And having taken this thing as of bad augury, it was with much ado that he gave me medicine. And many times he would have left me, thinking that he would run not a little risk from having cured me, or rather having finished my cure."—*Vita di Benvenuto Cellini*, lib. ii, cap. xi.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following were the questions on Anatomy and Physiology, and Pathology and Surgery, submitted to the candidates at the written examination on the 8th instant. *Anatomy and Physiology:* 1. Describe the Eustachian tube, its relations to surrounding parts, and its functions. 2. Describe the acts of mastication and deglutition, mentioning the muscles concerned therein, and the nerve-centres by which these muscles are controlled. *Pathology and Surgery:* 1. Describe the process of separation of a sequestrum in necrosis of the lower jaw, and the mode in which repair is effected. 2. Describe the characteristics of the chief forms of ulcer affecting various parts of the mouth, and their treatment.

The following were the questions on Dental Anatomy and Physiology, and Dental Surgery and Pathology. The candidates were required to answer at least two out of the three questions in each department. *Dental Anatomy and Physiology:* 1. Describe, in relation to human and comparative anatomy, the chief methods by which teeth are fixed in their place; and give examples. 2. Mention the changes which the lower jaw undergoes during the development of the teeth from birth to puberty, and account for its elongation backwards. 3. Describe the structure of the tooth-pulp in its earliest stages of formation, and in the adult tooth. *Dental Surgery and Pathology:* 1. Describe, and give the reasons for the manner in which the operation of extraction should be performed on different teeth; and mention the chief reasons which may necessitate the operation. 2. State the symptoms, sequelae, and treatment of dental periostitis; and explain in what respects they differ from those of inflammation of the dental pulp. 3. Enumerate the different irregularities in position which the inferior dentes sapientiae may exhibit. State the symptoms which such irregularities occasion, and what treatment you would adopt.

## THE SALE OF POISONS ACT.

Sir,—In the excellent paper by Dr. Althaus in the JOURNAL of February 2nd, on "Physicians' Fees and the Sale of Poisons Act", he has shown clearly the dangers to patients, and losses caused to medical men, by the repeated use of prescriptions. While practising in Scotland for some years, I have seen prescriptions of mine which in the cheap scale of fees then prevalent had cost the patients 2s., used again and again, not only for the patients themselves, but for their friends; the druggist being the only one to benefit, he sometimes getting twenty shillings when I had received two, or even not that. That, and the fact that the same druggist made my prescriptions public property, compelled me, unwillingly at the time, to keep my own drugs. Having now been for some time in England, I consider the English general practitioners' system, of always supplying their own drugs, much the best, both for them and their patients, and would not go back to the Scotch system if I could.

Pesides this point, however, I wish to call attention to a very serious defect in the Act above quoted, in the large quantities of drugs containing opium and other dangerous narcotics, which any druggist is at liberty to sell without any prescription, and with no restriction whatever except the putting of a poison-label on the bottle, etc. I have been a severe sufferer by this laxity, my wife, I am sorry to say, having, through ill health, contracted the habit of laudanum drinking—a habit I have found it impossible to check in any way, so long as the law allows and druggists sell, without question, such quantities as one, two, or even three ounces of laudanum, or even more, to one person in a day (I am not certain she ever used so much), and do so to children of seven or eight years without let or hindrance. One scoundrel, even after I had warned him that she was killing herself with it, actually supplied a messenger sent by her, on credit, rather than lose the paltry profit obtainable by selling an ounce.

As you may imagine, the misery caused in a household, as well as the injury done to my practice and the hindrance to scientific work of any kind, are very great; and as I am by no means alone, I believe, in my misfortune, others suffering in the same way, surely something could be done. Were the amount saleable without a prescription limited to, say, one drachm, it would be a great check on such cases as are at all similar to my wife's, as she can only get it hurriedly, and could not possibly get more than about two drachms a day. It is the facility with which she can get any quantity that has ruined her. I now give her half an ounce daily, rather than try to check it any more, but fear that she will only add that to what she gets elsewhere.

Could you kindly favour me by answering the following questions I shall be greatly obliged. 1. Are you aware of any other Act besides the Apothecaries' Act (1868) under which there is any restriction in the quantity of poisons saleable? 2. Having given the druggist of whom I have spoken warning that I am supplying my wife with as much laudanum as I consider safe for her, would he be liable to be indicted for culpable homicide if he knowingly and wilfully supplied her, or a messenger known by him to come from her, with such doses as I have spoken of above, and she were to die under the effects of such an overdose? I have several times already had some difficulty in restoring her from overdoses which she has taken herself while under the influence of the drug.—Hoping you will think this matter worth your attention, I remain, yours faithfully,

February 1877.

OHNE HOFFENUNG.

Sir,—Dr. Althaus's well timed article on "Physicians' Prescriptions and the Sale of Poisons Act" will not, I sincerely hope, be permitted to pass unheeded by the profession. In my opinion, there is no more vital point in medical jurisprudence than that referring to the loose and purposeless manner in which poisons are permitted to lie about the dwelling-houses of the population of this country, and the ready way in which these poisons are obtainable by the general public. It seems strange, but it is no less true, that patients now-a-days are not satisfied with medical opinion upon their case, but they must also have a lecture upon the therapeutic action of the drugs contained in their prescription; and if the physician politely and sensibly bow them to the door without giving them the information they look upon as a matter of right by fee, they then appeal to the pharmacist, who soon helps them out of the difficulty. No one but the medical profession and pharmacists can estimate the large amount of evil arising from this cause; in fact, I have known more than one instance where the pharmacist, contrary to his own interest, has declined to place in the hands of his customer the large amount of chloral which had been ordered in a prescription. I am sure there are very few pharmacists who would decline to be guided by the counsel of the medical man in this matter, until some kind of legislation can be framed to help us out of one of the most distressing and increasing evils of our time.—Very truly yours,

Hornsey Lane, N., Feb. 4th, 1878.

THOS. STRETCH DOWSE.

Sir,—An article by Dr. Althaus in the JOURNAL of February 2nd, on "Physicians' Prescriptions and the Sale of Poisons Act", has reminded me of some evasions of the Sale of Poisons Act which have come under my notice within the past twelve months. A grocer in this village has set up an amateur chemist's shop, he not having any licence to do so, and at one time supplied the people in this neighbourhood with laudanum to any amount they chose to ask for—e.g., a patient of mine, who was suffering from cancer, and did suffer great agonies, sent to him for some

and received an ounce and a half bottle full, labelled, "The draught to be taken immediately". Fortunately, the patient was rather a sharp man, and did not "take the draught immediately", otherwise the consequences can be very easily imagined. On this coming to my notice, I had a stop put to his sale of laudanum; but he still sells paregoric, castor-oil, and other drugs. Since he has stopped the sale of laudanum, the people send to the chemists in Gloucester, and get threepence worth from each of four, so as to get a pretty good supply. I have reason to believe that one man overdosed himself with some obtained in this manner, and went off into a sleep, from which he never awoke. Not very long ago, I was in attendance on a farmer who was ill, and one day, when I was in his room, I saw on the table a pint bottle nearly full of laudanum. I asked him where he got it, and he informed me he could get as much as he liked of it from the chemists. When things like this—which I dare say a great many other surgeons have also noticed—are allowed to go on, the Poisons Act cannot be of much service.—I remain, sir, yours obediently,

Frampton-on-Severn, Feb. 12th, 1878.

R. E. BURGESS, M.D.

The letters of Dr. Farquharson, Mr. Henry Brown, Dr. Ashburton Thompson, Dr. Ogle, Mr. Crossman, Mr. W. J. Marsh, etc., are deferred for want of space.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Post; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Derbyshire Courier; The Auckland Times and Herald; The Auckland Chronicle; The Western Mercury; The Daily Courier; The Lincoln Gazette; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Mashro Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Richmond and Ripon Chronicle; The Cambridge Independent; The Madras Mail; The Ashton Reporter; Saunders' News Letter; The Western Mail; The Bath Chronicle; The Bolton Chronicle; The Lincolnshire Chronicle; The Chippendenham Chronicle; The Crewe Guardian; The West Sussex Gazette; The High Peak News; The Cardiff Times; etc.

## CLINICAL REMARKS

ON

## THE STUDY AND DIAGNOSIS OF SKIN-DISEASES.

By ROBERT LIVEING, M.D., F.R.C.P.,

Lecturer on Dermatology at the Middlesex Hospital.

IN the following remarks on the best method of observing diseases of the skin, I would point out, in the first place, that the diagnosis of a disease, to be of any practical value, includes much more than assigning to it a name: it involves a correct estimate both of its nature and of its affinities. The great majority of skin-affections are forms of inflammation, and as such are very much alike as regards details, though they may differ altogether in other important respects. Thus, in almost all inflammations of the skin we may chance to find red patches, papules, vesicles, blebs, pustules, scales, or crusts; and, therefore, the first point of importance is the recognition of the fact that these varying phenomena of cutaneous inflammation are simply brought about by the anatomical structure of the skin, and are, therefore, of uncertain value in determining the nature of the inflammation. The extent and degree of the inflammation, the tissue involved, the grouping of the eruption, and the part affected, may all be of more importance than the minute characters of the elementary changes. But, although I wish at the outset to guard against an overestimate of the diagnostic value of minute characteristics, I nevertheless attach considerable importance to them, especially in certain cases, as I shall hereafter explain.

"For the recognition of a disease of the skin," says Hebra, "no other assistance is required than a knowledge of the objective symptoms, which are visible on the surface of the body in each particular case. We do not attach any value whatever either to the history or to the subjective phenomena in investigating a cutaneous affection, for we ought to be guided in this matter only by those symptoms which are appreciable by the sight, the touch, or sometimes by the smell. These afford certain and infallible grounds for the establishment of a diagnosis, for they have their origin in the malady itself. They are, so to speak, the alphabet of which the letters are traced on the skin; and our task is but that of deciphering the writing."

This statement of Hebra, that we do not attach any value whatever either to the history or to the subjective phenomena in investigating a cutaneous affection, must be received with reservation. It is, however, valuable, inasmuch as it tends to impress strongly and, as it were, to exaggerate the leading feature in our means of diagnosis. On the other hand, though an expert of Hebra's experience may possibly dispense with the aid of history and subjective sensations, yet few will doubt that in ordinary practice the history of a case may be of great use in enabling us to arrive at a correct diagnosis. For example, scabies in children is sometimes masked by an unusually copious eruption of eczema. If, however, in a doubtful case, we learn that several members of a family are coincidentally suffering from a similar affection, there will be presumptive evidence that the disease is scabies. No doubt the answer to this is, that we have the means of proving positively the nature of the malady by demonstrating the presence of the acarus. Yes; but this mode of proof is not always convenient, and in some cases where treatment has been already commenced, not even possible. In such a case, the history may be of great diagnostic value. Again, even the "subjective phenomena" are useful in determining the nature of a skin-affection. We have not unfrequently to deal with mild cases of intermittent urticaria, an affection which is often of such a transitory nature that the wheals and even the irritability of the skin may have vanished at the very time when the patient presents himself for examination, and consequently we have to draw our conclusions from the history and the subjective sensations of burning and itching described by the sufferer. I have said enough, however, for the present, to show that Hebra's dictum must not be pressed too closely in actual practice.

I. In order to make a successful examination of a patient suffering from skin-diseases, it is very necessary to have some systematic method of procedure. The rule of the first importance in all cases is, to examine the different parts of the body on which any eruption is present. For this purpose, it is not generally necessary to expose a large cutaneous

surface at one and the same time. The parts of the body should be examined in succession, and the state of each noted at the time of examination. The importance of this rule can scarcely be overestimated; indeed, in some cases, it is almost essential to a correct diagnosis. Everyone is acquainted with the fact that dermatosyphilis may be present in no less than five or six different forms of eruption in one and the same individual; and further—and this is the point—some of these forms may be highly characteristic, while others would hardly serve as means of diagnosis. Under these circumstances, a partial examination might lead to grave error and entail an unsuccessful course of treatment.

II. In conducting an examination, the following points should be kept in mind. Our object is, in the first instance, to take a general view of the efflorescence as a whole, irrespectively of the particular elementary forms of eruption present (vesicular, papular, etc.). We do this almost instinctively, and comprehend at a glance the importance of combination and arrangement, or in other words, that this or that elementary lesion, taken singly, does not constitute the skin-disease. Thus, when we speak of a vesicular, papular, pustular, or squamous skin-disease, we convey but a very imperfect idea of its nature. The parts of the body affected, the tissues involved, the form, arrangement, and grouping of the eruption, the degree of inflammation, and many other points, are often of more importance than the minute anatomical details. The mode, then, of speaking of skin-diseases as papular, vesicular, or pustular, must be regarded as an abridged form only, and analogous to shorthand writing.

Having, however, in the first instance, regarded the skin-disease as a whole, we may proceed, in the second place, to take cognisance of those separate parts which, combined, constitute the affection; or in other words, we may, as it were, dissect the eruption into its component elements.

1. In any given case under observation, we must distinguish what is essential from what is non-essential or accidental; what belongs to the original affection from what has been superadded; and we should select for especial examination those portions of the skin in which the disease is least complicated. For example, in order to demonstrate the presence of the itch-acarus, we do not choose a part of the body that is thickly covered with eczema, but we endeavour to find it in a patch of soft skin nearly free from secondary inflammation. Endless examples might be given of the modifications that skin-diseases undergo from being complicated with such common inflammations as eczema and urticaria, or even from the excoriations produced by constant scratching or injudicious treatment; but enough has been said on this point to suggest the necessity of care in distinguishing the essential from the accidental.

2. We should note the extent to which the anatomical elements of the skin are affected; whether, for example, the disease is merely confined to the cuticular layer, or whether the true skin is also involved; whether the hairs or sebaceous glands are affected; whether there are any alterations in pigmentation and colour. The importance of these inquiries is evident, as they lead us to determine by observation the original anatomical seat of the disease and the extent to which the neighbouring tissues are implicated. In order to ascertain these points, it is necessary to be acquainted with the character of healthy skin—that it is soft, smooth, elastic, and slightly greasy—that great differences in thickness and colour may be natural and compatible with perfect health; that the smoothness and texture of healthy skin vary greatly in different parts of the body, being generally thicker and rougher on the exposed sides than on the flexures or inner aspect of the limbs; that certain variations in the growth, colour, and texture of the hair, as well as of the skin, depend upon the age, sex, or race of the individual, and may be regarded as normal rather than pathological.

Bearing in mind, then, the conditions of healthy skin, we are in a position to examine in detail the abnormal changes in its various component parts.

a. In investigating the condition of the epidermis, it is easy to see whether the surface is unusually roughed, cracked, dry, or scaly; whether it is thickened by the accumulation of epithelium, as in psoriasis, or abnormally thin and transparent, or whether its outer layers are raised by the formation of blisters, vesicles, or pustules. By the aid of a common magnifying glass, we can further determine the state of the orifices of the follicles, whether they are plugged with sebum, as in comedones, or pouring out an abnormal quantity of oily secretion, as in some forms of steorrhoea. And lastly, we may observe whether papules exist, formed either from the hair follicles, or by enlargement of the existing papillae of the skin.

b. Any alterations in the true skin will also demand our attention; and here the hand may often aid the eye in the process of investigation. The tense and brawny feeling due to excessive infiltration is

better determined by touch than by sight. Again, in furuncular diseases the extent to which the inflammation involves the deeper tissues may be often more easily felt than seen.

c. Our attention should also be directed to the colour of the skin. Divergence from the normal hue may be due to an altered degree of vascularity, to hæmorrhage, irregular pigmentation, jaundice, or other causes. If redness be the result of increased vascularity, it will disappear for the moment under pressure of the finger, as in urticaria. If, on the other hand, the colour be due to hæmorrhage, it will be unaffected by pressure, as in purpura or a bruise; and in this case we further note the various changes which the hæmorrhagic patch undergoes, from different shades of red and purple to green and yellow, until it finally fades away entirely. Pigment-spots do not undergo rapid changes; moreover, the colour is generally some shade of brown, while the absence of pigment is marked by perfectly white patches. Alterations in pigmentation are especially common in dermatosyphilis, elephantiasis Græcorum, chronic eczema, psoriasis, prurigo, and alopecia areata; while, in some leucodermic affections, an irregular or defective pigmentation constitutes the whole disease. In determining the degree and kind of changes met with in pigmentation, some care is required. The extremely dark skin natural to some people may lead us into the error of supposing that the development of pigment is abnormal, while in leucodermic and allied affections we may easily be deceived by the effect of contrast. The skin around a white patch always appears darker than it really is; on the other hand, we must not forget that there is sometimes a true abnormal accumulation of pigment in the neighbourhood of leucoderma. Again, the deficiency of colouring matter in a patch of skin affected with alopecia areata might escape observation, though every one would notice the light colour of the hairs first reproduced.

d. In affections of the beard, scalp, etc., it may be necessary to make an examination of the hair, both shaft and root. By extracting one or two with a pair of forceps, we determine at once whether the force required for their removal is less than in health, and also whether the hair itself is abnormally brittle, as in common ringworm. Subsequently, we may examine one of the hairs under the microscope, first without and then with a little liquor potassæ, which renders it more transparent; we shall thus be able to note any change or abnormal growth in the structure of the hair and its bulb. This is especially important in dealing with doubtful cases of tinea tonsurans or favus.

In most affections of the skin and hair, some cutaneous regions may be found in a healthy condition, and we must use these for comparison with the unhealthy parts, just as in diseases of the lungs we are in the habit of comparing the sound with the unsound side of the body, or as we compare a shortened limb with its fellow of the opposite side.

3. The form or shape of the patches of eruption must be next considered. In order to impress the importance of this point, it will only be necessary to illustrate it by examples. In syphilis, the prevailing shapes assumed by the eruptions and ulcerations are circular, horseshoe, and gyrate. In ringworm, the original patches are circular. Zoster follows the course of particular nerves, hence its characteristic forms. Gutta rosea and erythematous lupus are often butterfly-shaped; the patches of erythema nodosum are rounded or oval and tumid. Many other examples might be given, but enough has been said to call attention to the fact abovementioned, and to indicate its possible value in diagnosis.

Hitherto, I have considered only the component parts and forms of separate patches of eruption, complete in themselves, but occupying, it may be, circumscribed areas. It is often, however, necessary to extend our field of observation and compare or contrast eruptions of one or more kinds met with at the same time in different parts of the body. As I have before stated, the coincident appearance of different kinds of cutaneous eruption in one and the same individual is one of the characteristics of syphilis.

III. I pass on to consider, in the next place, the subject of locality and its bearings on diagnosis. Some skin-affections are strictly local, not only in contradistinction to general, but also as being located in certain regions of the body only. As a rule, when eruptions appear on various parts of the body at the same time, we may suspect either a constitutional tendency to the malady or a specific poison pervading the system. The efflorescence of fevers and syphilis is an example of the latter; that of psoriasis and eczema of the former. Some diseases, however, are invariably confined to certain localities, as, for example, acne rosacea to the head and neck, syccosis to the hairy parts of the face. Other affections never invade certain regions; thus, scabies in adults is never present on the face or scalp, or acne on the soles or palms. By a process of exclusion, then, we should never apply the term acne rosacea to a red patch situated on the thigh, or call an eruption on

the face scabies. Other skin affections, while they are not strictly confined to one locality, yet have a marked preference (if I may use the expression) for certain regions. For example, erythema nodosum is common on the legs, acne on the face and shoulders, pityriasis versicolor on the trunk, lupus on the face, lepra on the extensor sides of the elbows and below the knees, alopecia areata on the scalp and eyebrows; to these many more might be added. Let us take an example in point; if we meet with an eruption, say on the soles of the feet, we know at once that it is either scabies or eczema (probably dry and cracked, and often mis-called psoriasis) or dermatosyphilis, for these are the only diseases (with rare exceptions) that affect the soles. The conclusions I would draw from these remarks is, that the locality of the eruption is an element of importance in our diagnosis.

IV. Hitherto I have dealt exclusively with those phenomena in skin-affections which are at once appreciable by our senses of sight and touch; namely, the character of the eruption, the tissues involved, the degree of inflammation, the shape of the patches, and the regions affected. These are all patent to our observation; and for these observations and the conclusions to be drawn from them we are exclusively responsible. There are, however, other means of diagnosis, less perfect in their nature, and less under our immediate cognisance. I refer to the subjective sensations of the patient himself. The more important of these are sensations of itching, burning or tingling, and darting (neuralgic pains). With regard to the first of these—namely, itching—we are not dependent entirely on the statement of our patient. On the contrary, we may often determine the presence of itching by the well-known marks produced from scratching; and the study of these marks affords a not unimportant field of observation, for some skin-diseases derive their most characteristic features from being scratched. For example, prurigo from pediculi consists of a papular eruption which would often escape observation—does, indeed, in the paralysed—if the process of scratching did not remove the tops of the papules and lead to a slight hæmorrhage. It is the little spots of coagulated blood which especially attract our attention, and give to the disease its most striking and distinctive feature. Sensations of burning and tingling are characteristic of all forms of urticaria and allied affections, and are present also in gutta rosea; while acute neuralgic pains are often attendant upon zoster, and are occasionally met with in alopecia areata and urticaria. The traces of scratching are often, as I have said, very characteristic. In prurigo, scabies, and eczema, we have excoriations and little hæmorrhages produced on the surface of the skin; in urticaria, long red wheals or striæ; while in chronic affections of all kinds, attended with severe pruritus, we find an augmentation of cutaneous pigment, the result of the constant stimulation by scratching. To illustrate the importance of these signs as a means of diagnosis, it is only necessary to remember that, where they are present, we at once conclude that we have probably to deal with one of the following diseases; namely, scabies, eczema, lichen, urticaria or its allies, and prurigo or morbus pedicularis. The sensations of burning and smarting do not lead to any changes in the appearance of the skin, and consequently we depend for our information entirely on the statements of our patient.

V. We all recognise the importance of the history of a case in our ordinary diagnosis of disease; but it is not so obvious that, in dealing with skin-diseases, the same rule applies, and that we require to know the history before we can arrive at a complete diagnosis. Now, if the problem were merely to give a name to any particular skin-disease before us, it may be granted that this can be done without inquiry into the antecedents of the case; but if in a correct diagnosis we include, as we ought to do, something more than this, if we take into consideration all the facts in connection with it that may bear upon treatment or prognosis, then the history and general condition of our patient become matters of real importance. Let me illustrate this point. Suppose, for example, three patients present themselves in succession for examination. The first shows you his arms covered from the back of the hand to the elbow with a minute red papular eruption, attended with sensations of burning and itching. The eruption ends abruptly at the bend of the elbow; it is at once recognised as eczema in the papular stage. From the history, we find that his forearms have been exposed at cricket to a burning sun; we consequently conclude that the eruption is the effect of heat and exposure, and will probably disappear in a few days. In the second patient, there are red, excoriated, and weeping patches of skin on the inner sides of the thighs, the axillæ, and other parts of the body, which are evidently eczema; and we further find that our patient has been for some weeks rubbing into the skin a strong sulphur ointment, with the view of curing a real or supposed scabies. Here, again, we have to deal with an eczema, but one developed from different causes and under different circumstances. In this case, a discontinuance of the use of the sulphur ointment will

probably lead to a rapid cure. In the third case, a middle-aged man suffers from dry, scaly, and very irritable patches about the flexor sides of the limbs. This is still eczema; but we learn that he has had similar patches on several previous occasions, and that he has had gout more than once. We know then that we have to treat chronic eczema in a gouty man, and we adapt our remedies to meet the case. In all these three instances, then, the name of the eruption is identical. In all three, we have to deal with eczema, but eczema of different kinds, and produced in very different ways. Merely, then, to pronounce a skin-affection to be eczema is, I maintain, but a *very imperfect diagnosis of the disease*. We are so apt to be deceived by a mere name! The diagnosis of any malady is only valuable in as far as it leads to correct treatment and prognosis, and any method that stops short of this is a very imperfect one. In other words, the etiology of a disease is in many cases inseparable from the diagnosis.

From what I have said, it will be inferred that I use the expression "history of a case" in a comprehensive sense, and include the following points, which all bear more or less on a full and complete diagnosis: (1) Age and sex of the patient; (2) Occupation or mode of life of the patient; (3) Past history; (4) Present condition.

With regard to (1) the age and sex of the patient, I would only remind you that certain skin-affections, like the diseases of other organs, are almost unknown at particular periods of life, and that some diseases are exclusively confined to one sex. For example, acne is not met with in babies, or syphilis in women. Tinea tonsurans of the scalp is an affection of children, and pityriasis versicolor of adults. True ichthyosis is a congenital affection, and therefore may be excluded when we have to deal with a disease making its first appearance in adult life. (2) With regard to occupation and mode of life, it will be sufficient to indicate that certain skin-affections are produced by particular occupations, and that others are common only amongst certain classes. (3) The past history includes both that of the *patient* and of the *eruption* attack. The past history of the *attack* must be in many instances of primary importance. Thus, for example, we may have to deal with cases of urticaria, in which the visible effects on the skin are the same, but which spring from very different causes. One may be due to poisoning by shell-fish, another to a continued course of copaiba, a third to the irritation of pediculi, and a fourth may be purely an affection of the nerves. To be satisfied, then, with the mere name (urticaria) would be as unreasonable as it would be to treat all four cases in the same way. In order to arrive at the past history of the patient, it will often be advisable to draw our conclusions from indirect questions and observations. Thus, in investigating a suspected syphilitic eruption in a woman, the indirect method is almost always preferable. Often the nature or even the existence of the primary inoculation is unknown to the patient, while she is well aware of having suffered from ulcerated sore-throat, or nocturnal pains, or of having miscarried. But we are not always dependent on the statements of our patients in arriving at conclusions as to their past history. Scars are often left on the skin or about the fauces which are silently eloquent of former disease.

In stating that the general condition of health is inseparable from a comprehensive diagnosis of skin-affections, nothing more is intended than that diseases of the skin, like the diseases of other excreting organs (for example, the kidneys), are often associated with certain constitutional states or diatheses, and sometimes with special diseases of other organs; in other words, that the skin-affection, in many instances, cannot be regarded simply as an uncomplicated local malady. These remarks apply especially to such diseases as small-pox, chicken-pox, syphilis, and elephantiasis Græcorum, where the skin-affection is only a small part of the malady; but also in a less degree to such affections as eczema and psoriasis, which are so often associated with either a gouty or scrofulous diathesis. But, further, we often find skin-affections influenced by disease of particular organs. For example, not long ago, I had under my care in the Middlesex Hospital two severe cases of the pityriasis rubra of Hebra, associated with chronic albuminuria, and we remarked in both cases that when the condition of the skin improved for a time the albumen diminished, and *vice versa*; this occurred so many times that it would be impossible to regard it as an accidental coincidence. It is immaterial for the purpose of my illustration whether the temporary improvement in the action of the kidneys produced a change in the skin, or *vice versa*. The fact that some skin-diseases, such as scabies, are purely local, does not in any way disprove the truth of my proposition, that we must regard a pathological condition of the skin just as we should regard a pathological condition of any other organ of the body, and that without this our *diagnosis is incomplete*.

To sum up the foregoing remarks, we may lay down the following brief rules for our guidance in the examination of diseases of the skin. 1. Examine all parts of the body in which an eruption is present; 2.

Take a general view of the eruption regarded as a whole; 3. Separate it into its component parts, and distinguish what is the essence of the disease from what has been superadded; 4. Notice the tissues involved, and the presence or absence of infiltration, induration, etc.; 5. Notice the form or shape of the patches of eruption; 6. Observe the locality affected; 7. Investigate the subjective sensations of itching; 8. Ascertain the past and present history and general condition of the patient.

## ON THE ACTION OF MEDICINES, OLD AND NEW.

By JOHN KENT SPENDER, M.D. Lond.,

Surgeon to the Mineral Water Hospital, Bath.

### IV.

*Succus Conii*.—Towards the close of my last paper (BRITISH MEDICAL JOURNAL, July 24th, 1875, I directed attention to some preparations in the *Additions to the British Pharmacopœia* of 1867, and I spoke of the value of the juices, or *succi*, that had been lately introduced. It is remarkable how slowly some things win official acceptance. In 1864, Dr. Garrod wrote that these preparations (the *succi*) had been for some time in medical use; for the first time three were then made official, and two more were added in the Appendix. Five juices are the rather meagre resource which pharmacy has offered us in this department: of the *Pharmacopœia*. Of more importance, however, than the penury of pharmaceutical skill is the official dosage, which in this case is certainly misleading. What sort of value, asked the late Dr. Anstie, can be attached to the statement that the *succus conii* may be given in doses of from thirty to sixty minims? It had been recognised for some years past that four or five drachms may be often given without the production of any marked physiological phenomenon; and even ounce-doses of this juice (prepared by a first-rate manufacturing druggist) have been administered without producing any recognisable effect whatever.

Conceding the possibility of a substance having important therapeutic powers and yet causing little physiological disturbance in the healthy human body, it is at least very unlikely that a fluid drachm-dose of any drug will be of much use if an ounce-dose can be taken with impunity. Now, it has been asserted that no poison, except prussic acid, excels conia in the subtlety and rapidity of its operation; and, when introduced into a vein, the fatal effect is almost instantaneous. Hence we can draw an approximative conclusion of the comparative inertness of the official preparations of conium. Dr. Stille relates of Dr. Pliny Earle, that he took experimental doses of extract of conium in order to discover how much he could bear. Beginning with a grain three times a day, he gradually augmented the quantity until, on the fifteenth day, he took at each dose twenty-five grains. The effect was "such a fullness in the head as might be caused by a ligature around the neck, together with some vertigo". Forty-five grains on the following day caused a repetition of the same sensations, "with the addition of weakness and weariness of the knees and a vacillating gait". And John Hunter records that, in a case of phagedænic ulcer resulting from bubo, he administered extract of hemlock in doses gradually increased to two ounces and a half a day. Dr. Stille justly remarks that the enormous doses of conium required to produce the effects described in Dr. Earle's experiments, render it certain that the preparation used by him was very feeble. In an early number of the *American Journal of Medical Science*, Dr. Fountain tells us of very different and even dangerous results from taking twelve grains of an extract prepared from the seeds at a temperature below the boiling-point.

It was Dr. Neligan who first used or praised the *succus conii*; and, when the average dose recommended by so high an authority was only thirty minims, there may be an apology for the official standard being misleading. In my last paper, I gave the outlines of a case of violent "hysterical chorea", occurring in a married lady of forty-six or forty-seven years of age, so turbulent and exhausting as to induce some fears of the possible issue. Three ounces of hemlock-juice were consumed daily for several days with a very happy therapeutic effect; and I am now able to add that since this illness (in 1874) there has not been the slightest return of the malady. I may remark here that in the *United States Dispensatory* there are two preparations, called respectively the alcoholic extract of hemlock and the fluid extract of hemlock.

*Hyoscyamia*.—Considering that *hyoscyamia* has been lately proposed as a remedy for acute mania, it is rather remarkable that both Hippocrates and Dioscorides speak of large doses of henbane as capable of exciting delirium, which was compared to the delirium of drunkenness. The more valuable of the modern researches on the action of hyoscyamia begin with a contribution by Dr. Oulmont in the *Practi-*

tious (January 1873); and in the same journal for July 1876 there is a paper by Dr. Robert Lawson on the therapeutic actions of the same alkaloid, discussing chiefly its effects in mental diseases. More recently still, Dr. Ringer has recorded an instance of acute mania treated with hyoscyamia, and its results compared with those of atropia and daturine; the conclusion being that, so far as the production of sleep is concerned, atropia and daturine do nearly as well as hyoscyamia. In my early days of practice (1853), I had under my care a case of acute mania in the person of a dissenting minister, above sixty years of age; his brain had been wrecked by a combination of worry and work. The noisy misery of this poor man is even now vividly before my eyes and ears; and to show the helplessness of therapeutic doctrine in those days, two of the best men I could get in consultation had nothing to propose but the administration of comparatively large and frequent doses of tartar emetic, with the object, I imagine, of forcibly beating down the rebellious nervous system. And very soon quenched in death that nervous system was. The blessings of recent therapeutic inquiry are shown in the new management of these fearful overthrows of brain-function; and to the practitioner of the present day delirium has lost half its terrors. Thirty years ago, delirium tremens was treated with opium, and sometimes more alcohol; and it was not very unusual for the patient to die suddenly in a state of poisoned collapse.

*Eczema.*—There is a tradition, not yet quite demolished, that grave neurotic and other maladies may be caused by the "retrocession" of certain diseases of the skin, principally of the eczematous group. For instance, a child who is suffering from rather severe eczema of the face and limbs has a feverish attack, and it is found that the eruption partially disappears from the skin; the moisture has dried and the irritation has subsided. When the fever leaves, the cutaneous symptoms recur; and it is possibly inferred that there has been a metastasis to internal organs. Hebra ridicules the theory in his own way, and points out that the abatement of the disease of the skin is caused by the anæmia of the integument which is the result of the febrile attack. Hebra adds that he only wishes that he could cure an eczema so suddenly and so easily! That there is an occasional neurotic element in eczema, as in other vesicular diseases of the skin, may be fairly conceded; for instances are on record in which a neuralgia and an eczema were interchangeable. But there seems no ground for the notion with which some medical men console their patients, that they had better bear their eczema in order to avert some serious internal disease.

In private and dispensary practice, I have seen during the last twenty years a vast deal of eczema, especially as it is seated on the lower limbs. Observation of one disease for so long a time brings to light some little points of pathology and treatment which cannot be learnt from books, even from the interesting monograph of Dr. McCall Anderson—*E libris nemo exiit artifex*. The principal text-books of diseases of the skin are silent about hygrometric conditions of the atmosphere, and their influence upon dermo-therapeutics. Yet this influence is not only most real, but is one of the keys to a prompt cure of our patients. Moist warm weather is adverse to the use of ointments, and often compels the application of lotions; while in cold dry weather ointments seldom disagree. But there are some skins, endowed with a special susceptibility, to which all greasy substances, however fresh and pure, are quasi-irritant poisons. However, here is the *crux* in the management of angry vesicular eruptions, that we cannot always tell beforehand what class of remedies will do most good, and most control abnormal tissue-growth. During the four hottest months, anything approaching to *eczema rubrum* ought to be treated with the assiduous application of the common black wash (*lotio hydrargyri nigra*), mixed with a tenth part by measure of glycerine. The application should be renewed three times in the course of twenty-four hours, and the dressing (lint or linen rag) soaked every time with warm water before removal. I discovered by chance the great utility of this method more than sixteen years ago; but I am not aware that it is recognised in any manual of cutaneous diseases. The late Dr. Hughes Bennett gave the very bad advice that wet applications to the skin should be covered with an impervious coat of gutta-percha or oiled silk; forgetting that the pent-up secretions would themselves be sufficient to cause an artificial eczema, and so the original malady might be perpetuated.

As a rule, the drier forms of eczema are quickly cured by the use of a lead ointment. There are several ointments of lead in the *Pharmacopæia*, and the *unguentum plumbi subacetatis compositum* is unquestionably the best. Mr. Balmanno Squire has devised an ingenious glycerole of subacetate of lead, based on the physiological action of glycerine on diseased epidermis. Mr. Wathen of Fishguard recommends strongly an ointment made with the liquor of subacetate of lead, some glycerine being rubbed into the lard before the liquor is added; and as much liquor should be added until the lard becomes

saturated and will not receive any more. In two or three cases, I have found Mr. Wathen's ointment very soothing, but I could not complete the cure with it. There seems, however, to be an entire freedom of risk from lead-poisoning. When the face is the seat of eczema, and there is much swelling around it, the inflammatory œdema should be first reduced by a lotion of oxide of zinc and calamine and lime-water, and then the so-called Kirkland's neutral cerate applied freely at night. A good formula for this cerate is to be found in Mr. Spencer Watson's work on *Diseases of the Nose and its Accessory Cavities*. I have found that the rather objectionable *puttiness* of this ointment may be got rid of by admixture of a little ointment of benzoated zinc. Both in Dr. Tilbury Fox's well-known work and in Dr. Liveing's *Treatment of Skin-Diseases* are some good prescriptions for lead ointment (see especially Dr. Liveing's Formula 83, *unguentum hydrargyri cum plumbo*).

I must not prolong my remarks on eczema; but I may add that it needs a practised eye to recognise the exact shade of this disease which is likely to be benefited by tar, and the strength of the ointment which should be used. As a rule, the drier the eczema the greater the probability that a successful treatment may be based upon tar externally and arsenic internally; for the quality of *dryness* means that all *exudation-process* has ceased, and that we have to deal with an *exudation-product*.

*Mercury.*—The ointment of mercury, or the old "blue ointment", has most undeservedly passed out of general use, except for the purpose of inunction. But, from twenty to twenty-three years ago, it was employed in some of the Irish hospitals as a local remedy for erysipelas, and was strongly recommended by Dr. James Hughes in the *Dublin Hospital Gazette* for May 15th, 1854. Without considerable caution, salivation may easily occur; but it is remarkable that a rapid improvement of local symptoms has been seen to follow salivation. I have notes of a case of erysipelas which happened in my practice in 1855. The wife of a tradesman, rather beyond middle age, of temperate habits, had general erysipelas of the face and scalp, with much fever. As the disease threatened to extend, I surrounded the neck with a collar (two inches wide) of mercurial ointment, and the application was kept up for quite two days. No redness or swelling appeared on the cardiac side of this boundary-line, and no mercurial intoxication marred the speedy cure of the patient. Dr. Hughes rather rashly covered the whole erysipelatous surface with the ointment, but flexile collodion (mixed with glycerine) is both more convenient and much less dangerous.

What a loss it is that popular, and even some professional, prejudice hinders the full rational employment of mercury. Trousseau describes a rheumatic inflammation now and then limited to a single joint; but there is a single arthritis of a severe kind in which there is no rheumatic pyrexia, and which is treated in a rapidly beneficial way by the administration of mercury in small and frequent doses. Take a case which has occurred to me within the last few days. The cook in a gentleman's family was seized at four o'clock one morning with a most agonising pain in the shoulder-joint, accompanied by some swelling. I saw the patient a few hours afterwards, and found all the local symptoms highly developed; the pulse was slightly quickened, but the thermometer was raised only half a degree. Iodide and acetate of potassium were given in a mixture, and two grains of blue pill with a little Dover's powder every two hours. After eight pills, a slight febrile was smelt in the breath, and they were at once suspended; but the relief of pain was very striking. The other medicines were continued for a short time longer, and the healthy mobility of the joint was quite restored within a week.

A mild "course" of mercury is often of great use in certain forms of chronic bronchitis in elderly people. There is just enough secretion to impede the free passage of air; there is a slight dusky hue of skin; a teasing cough; and often disturbed nights. Putting out of sight the remoter dangers of this state of things, it is clear that an embarrassed pulmonary circulation means delay in the general circulation, limited excretion, and imperfect tissue-change. Ultimately, therefore, bronchorrhœa not only impedes air reaching the blood, but impedes blood getting to the air. An occasional brisk aperient is most useful in counteracting this condition; but three grains of blue pill every night (with perhaps a little powdered digitalis and squill) go to the root of the mischief, and should be continued until the gums are in the slightest degree sore. Constitutional weakness or diathesis may, of course, forbid this treatment; and after the age of threescore and ten it is not to be thought of. Again, during the middle period of life, repeated catarrh in the chest may engender a spasmodic state of air-tubes, a quasi-asthma not very unlike the real disease, and sometimes leading up to it. It is very necessary to arrest this chronic inflammation before the *habit* of spasm is definitely fixed; and to this end no remedial plan

contributes so much as mercury administered carefully for a short time, provided that all other hygienic measures are steadily carried out. These points of practice were illustrated about twenty years ago by Dr. Theophilus Thompson, and more lately by Dr. Thorowgood.

The slightest suspicion of a "tubercular predisposition" would negative the propriety of any mercury being given internally. But I remember as a student the curiosity and wonder excited by Dr. Graves' mercurial treatment of acute miliary tubercle of the lungs, as related in his clinical lectures. Few disciples were so daring as the master; and it may be admitted that Dr. Graves' cases might have been grouped now under the head of syphilitic phthisis.\*

Another grand therapeutic use of mercury is in the management of some superficial diseases of the skin. All itching papular eruptions may be beneficially treated with perchloride of mercury; arsenic is poison to them. Some varieties of lichen are more controllable by perchloride of mercury than by any other medicine; and the same drug often drives away chronic forms of urticaria. There are few therapeutic combinations more valuable than perchloride of mercury and colchicum, especially in that chronic eczema in which the neurotic element of irritation causes trouble; and, in relapsing pemphigus, arsenic and perchloride of mercury together will sometimes succeed when the former alone has failed.

I conclude this paper with the expression of a wish that some means could be found of disguising mercury as it appears in prescriptions. The fatal abbreviation *hydr.* tells its own tale. There seems no valid reason why the letter *h.*, or the chemical symbol *Hg.*, might not do medical duty, and prevent practitioners from being embarrassed by the inquisitiveness of their patients. An eclectic therapeutics will learn the true doctrine of all powerful medicines, when to give them and when to refrain; and the right use of mercury, as of venesection, is probably one of the severest tests of therapeutic skill.

## BATH THERMAL MINERAL WATERS: THEIR USES AND ABUSES.

By A. B. BRABAZON, M.D.,  
Physician to the Bath Mineral Water Hospital.

### II.

*Gout.*—I now come to the consideration of the therapeutical powers of these mineral waters as regards gout. In considering the subject, I beg to be understood to refer to gout, only in its subacute or chronic form. Cases of acute gout rarely present themselves for treatment of this kind, though I have heard of *very* unfortunate consequences resulting to patients who, when suffering from acute gout, had been so foolish as to plunge into the thermal baths without previously asking or taking any proper advice. I also include in the category of gout cases of so-called "rheumatic gout".

The number of cases of gout submitted during the year ending May 1877 is comparatively small as compared with rheumatism. There were really ninety-seven cases discharged. For the sake of round numbers, I have taken eighty cases in the order of date of discharge. This number is made up of sixty-six males and fourteen females. The statistical tables are arranged in a similar manner to that adopted in rheumatism; and I will beg my readers to refer to these tables to enable them fully to understand any observations I may have to make. The total percentage of "cured" is not by any means so high in gout as in rheumatism, being in the proportion of 12.5 in the former to 22.1 in the latter. The highest average of "cured" is that among males between 20 and 40, being 24.2; but there is a remarkable diminution of percentage between 40 and 60, amounting then only to 3.2; thus showing the probabilities of cure, as far as immunity from pain and other symptoms may be called a cure, to be about eight times as great in the earlier double decade as in the later. Of females, there is but one discharged as cured, and that one over 60; but, as only two were discharged altogether over 60, we cannot strike a fair average. The total number of cases discharged as "much better" was fifty-eight: fifty-one males and seven females. I will here remark that the difference between the relative terms "cured" and "much better" is much less than is to be understood by the same terms as applied to rheumatism. I mean that, in gout, the "cured" may, in some instances, more probably be considered as "much better"; while, in rheumatism, the terms are much more absolutely distinct and appreciable. We find that twenty-five males were discharged "much better" between 20 and 40, and a similar

number between 40 and 60; this gives a percentage on the total discharged at these periods of 75.7 and 80.6 respectively. Why there should be a more favourable percentage at the later period of life, I cannot explain; but I will vouch for the fact. The percentage of results of treatment as regards females within the periods of life above mentioned is founded on a numerically small proportion of cases; but, taking into account the relative disproportion between the numbers of males and females treated—viz., sixty-six to fourteen—I think we may safely admit the percentages at these periods as equivalent to 66.6 and 44.4 respectively, showing a decided inferiority as to results of treatment as compared with those of the male sex. Under the head of "better", we find no males discharged under 40. From 40 to 60, inclusive, four males were discharged, giving a percentage of 12.9 on the total number of males discharged within this period; viz., thirty-one. On looking into the female statistics as regards the period between 20 and 40, we find one discharged "better" out of three cases; the percentage is 33.3; but I fear that the numbers are almost too low to enable us to draw perfectly reliable conclusions. Between 40 and 60, we may, I think, arrive at satisfactory results on sufficient ground, numerically speaking, and the percentage is 22.2. Thus it appears, regarding the period of life between 40 and 60, females apparently have considerably the advantage, in the proportion of 22.2 to 12.9. This statistical fact may be accounted for in one of two ways: either that really gout is more amenable to treatment in females than in males at this period of life: a fact which, I think, is controverted by the relative percentages under the term of "much better", or that the much larger number of males than females discharged under the heads of "cured" and "much better" leaves a comparatively small number to be accounted for under the terms "better" and "no better", and causes a small percentage accordingly. I myself incline to the latter opinion.

Finally, we arrive at those cases discharged "no better". We have but five cases to deal with—two males and three females—out of a total of eighty; making an average per cent. of 3.03 for males and 21.4 for females, the collective average being 6.2. Comparing this with the collective average per cent. of cases discharged "cured" and "much better"—viz., 12.5 and 72.5 respectively—there cannot be much room for doubt or scepticism as to the effect of the Bath mineral waters in gout, under proper conditions and under favourable circumstances.

It would be an act of presumption on my part to point out the well known complications and consequences of gout; their name is legion. I will venture so far as to say that much which I have said as to the conditions existing in rheumatism is equally applicable to its congener gout; but it should be remembered, in advising thermal baths, that the organic complications and consequences in the latter are, particularly as age advances, more serious than in the former: one is more likely to meet with arterial degeneration and consequent cerebral disease, or with fatty degeneration of the cardiac muscular tissue, or, again, with renal disease, all of which affections, according to degree, more or less affect the probabilities of improvement or the propriety of attempting treatment by thermal baths; but it should also be remembered that many cases in which hot baths might be injurious, or even dangerous, will be materially benefited by the internal administration of the "waters".

My own experience leads me fully to endorse the opinion recorded by Dr. Garrod, that mineral baths should be avoided where there is much structural disease of the heart or kidneys, or when an acute attack of gout is impending; and I think this remark is equally applicable to an impending subacute attack.

I will conclude these few observations by expressing my individual opinion that, as a general rule, the Bath mineral waters will be found more beneficial in cases of atonic gout, or where there is a somewhat debilitated habit of constitution, than in those of the sthenic or acute kind: though I do not mean to say that, under proper conditions, cases of either description will not derive benefit from their careful administration.

The influence of the baths upon the local conditions arising in gout depends, of course, on the degree and kind of these conditions. Thus joints which have been the objects of attack for the first or second time, in which perfect mobility may have been partially and temporarily interfered with, and in which all acute local symptoms have subsided, will, I have no doubt, regain their normal condition under such treatment. But, again, I do not believe that this or any other treatment will restore mobility to joints which have been the seat of disease for a lengthened time, and in which cartilages, synovial membrane, ligamentous structure, and the sheaths of the tendons around these joints, have become the seat of gouty deposits in the concrete form of urate of soda; but, even in these unhappy conditions, the element of pain is to be taken into account, and great relief may be expected from the use of the waters. Between the extreme cases which I have attempted

\* A recent monograph by Dr. Charteris affords a clue to the more hopeful treatment of "acute phthisis".

to describe there are very many indeed in which most satisfactory results may be almost confidently expected.

*Sciatica; Lumbago; Coxalgia.*—I have placed these diseases together because, as far as constitutional causes are concerned, they may be considered to be similar; and any remarks I have made, and any statistical deductions I have drawn, are equally applicable to them; but sciatica, I think, deserves more than this passing notice, both in respect of its comparative frequency and the generally severe pain which accompanies this occasionally intractable affection. Forty-six cases of sciatica were discharged from hospital during the years 1876-77: forty-two males and four females. This fact shows the much greater frequency of the affection in males than females. Under 20 and over 60, the disease appears to be rare. The period between 40 and 60 appears to be most favoured; in fact, the numbers discharged under 20 and over 60 are scarcely sufficient to afford decided results. The percentage on the male side of "cured" under the remaining two periods are sufficiently favourable to attract special notice: 36.5 and 13.2 respectively. The percentage also of those "much better", at the same period, is also remarkable, being 50.0 and 76.6. The contrast between these favourable results and those of patients discharged "no better" is very striking. Taking these same periods, 20 to 40 and 40 to 60, we find the percentage in the latter as 12.5 and 3.3 respectively. On the female side, four cases are scarcely sufficient on which to build an average, and therefore I will leave it to my readers to attach what significance they may think proper to the results as recorded in the table.

Of sciatica generally, and of the purely local or neuralgic forms of the disease particularly, I will say that, as far as my own experience goes, I have found no other form of disease more likely to be cured or relieved by these mineral waters, though occasionally supplemental treatment by galvanism or hypodermic injections of morphine may be advantageously employed.

Lumbago, as a term, is so very general in its application, that I must here limit it to the gouty and rheumatic forms, and also include lumbago as the result of injury or accident. The statistical table of lumbago shows only ten cases: six males and four females. The percentage of "cured" and "no better" among males calculated on total discharged is the same; viz., 16.6; 50 per cent. were discharged "much better". Among females, the percentage of those discharged "much better" and "no better" was in both 25; 50 per cent. were discharged "better". The numbers may be rather too small to arrive at just conclusions; but I fully believe larger numbers would develop statistical results even more favourable, as I am fully impressed with the notion that such affections of what I may be permitted to call fibro-muscular structures are in a high degree favourable for this special form of treatment. I shall not dwell on coxalgia specially; but I will beg of my readers to regard it simply in the light of a gouty or rheumatic affection causing pain in the hip-joint, to which the same remarks are applicable as to other joints similarly affected.

*Hemiplegia.*—I pass now to a class of diseases so important in their nature, and presenting occasionally such doubt and difficulty in diagnosis, prognosis, and treatment, that it is with great diffidence indeed I approach this part of my subject. I know I may probably express opinions on some points from which my colleagues, and others equally well informed as myself, may differ; but I beg to be understood to give those as derived only from personal observation and founded on personal experience. All the classes of diseases to which I have alluded may be treated with the thermal water, for a time at least, possibly with impunity; no harm beyond loss of time and some expense may accrue, although no good results may be obtained; but affections of the nervous system cannot be thus trifled with, and therapeutic agents even so simple and innocent as, according to some, are the Bath mineral waters will be employed either for "weal or woe" to the patient.

During the year 1876-77, thirty-two cases were discharged marked "hemiplegia": twenty-eight males and four females. No males and but two females were discharged under 20. The largest number discharged as to periods of life, consisting of nineteen males, was between 40 and 60. Out of thirty-two cases discharged there was but one cured—a male between 40 and 60. Probably a fair way of arriving at a legitimate conclusion will be to contrast the "cured" with those discharged as "no better". Taking males, the percentage of "cured" in those discharged between 20 and 40 is *nil*. The percentage of those discharged within the same period as "no better" is 16.6. Again, between the ages of 40 and 60, the percentage of "cured" to that of "no better" is as 5.2 to 36.8. Over 60 there are no cures recorded, nor are any discharged "much better". The percentage at this period of life, as regards those discharged "better" and "no better", is 66.6 to 33.3. The percentage of

"cured" among males total is 3.5; the percentage of those discharged "no better" among males total is 32.1. The percentage of males and females collectively is 3.1 "cured" to 28.1 "no better". I draw attention to the fact that it is only among those discharged under the term "better" that the percentages will be found higher than among those discharged as "no better". I candidly confess that I attach less distinctive signification to the term "better" than to the other three terms into which I have subdivided the cases. I shall submit these statistics to my readers, and leave it to them to judge whether or not they present a very unfavourable aspect as to results when contrasted with those of the diseases before mentioned.

*Paraplegia.*—As only four cases were discharged during the year, I need scarcely tabulate them in regular form; they were two males and two females. Two were cured, aged 12 and 29 respectively, both females. Of the two males, one was discharged "much better", aged 40, and one was discharged "no better", aged 57. It will be observed that the two cured cases were females, and I beg to draw attention to the ages. One was 12 and the other 29. As regards the one at 12, it is, I think, improbable that serious organic mischief of the spinal cord existed at this age; there are unfortunately no records of the case which I can find; but I would be inclined to suppose that such a case was the result of serous effusion, the consequence of spinal meningitis or possibly of congestion of the cord itself, brought on by cold, rheumatism, or tubercular deposit. Such a case, I can well imagine, would very probably be cured, and certainly improved, by such treatment as thermal baths. In the other case (also a female aged 29), I have no recorded history; but, without one, I confess to scepticism as to organic disease, and I would rather rely on some of the causes just mentioned as sufficient to produce the symptoms; adding to these possible hysteria. Of the case of paraplegia discharged at 40, a male, I have an intimate knowledge, as the patient was under my own care in hospital. He had been an engineer on the Great Western Railway, and, in a railway accident, received severe injuries, concussion of the brain and spinal cord amongst others. He was at first a patient in the United Hospital in Bath, and narrowly escaped fatal consequences of his severe injury. He was thence transferred to the Bath Mineral Water Hospital, with the hope that the symptoms of paralysis which remained might be improved by a system of baths. When admitted, there were symptoms of hemiplegia as regarded his face, which was distorted, and of paraplegia as regarded loss of power over both legs. He certainly left the hospital much better as regarded power of locomotion, and somewhat, but not so much, improved as regarded his articulation, memory, and other cerebral symptoms.

I mention this case particularly, as I consider it a typical one of the kind of paralysis which, I believe, may be and is frequently improved by the use of thermal baths, as contradistinguished from the class which I believe to be incapable of improvement. In the former class, I place cases where paralysis is what one might call acute, arising from mechanical pressure of serous or sanguineous effusion, in which there has been no disintegrative injury to the brain or spinal cord, and in which absorption of the effused material removes completely or partially the dependent consequences. In the latter class I place cases of chronic cerebral or spinal disease, whether it be softening or induration, or the effect of innutrition. I hold that, if disintegration of the tissue of the brain or spinal cord have taken place, it is perfectly useless to submit such cases, with a prospect of improvement, to mineral water treatment, whether applied internally or externally.

*Locomotor Ataxy.*—During three years, I can only find four patients discharged from hospital having been treated for this disease. They were all males, aged 26, 36, 42, and 57. The two patients, aged respectively 26 and 57, were marked "much better"; the two at the intermediate ages were marked "better". These numbers are too small on which to found legitimate conclusions; I can, however, add two cases which came under my own notice in private practice, and in which I carefully and for some time employed the baths and waters. I confess to having been disappointed in the results in both cases. I should mention that, in these cases, there was a gouty cachexia.

*Wasting Palsy.*—During the three years 1874-75, 1875-76, 1876-77, seven cases of "wasting palsy" were discharged from hospital: six males and one female. I may add to this case a private patient treated by myself aged 60, making eight in all. The number is scarcely sufficient for a statistical table of age and sex; but we can easily arrive at a practical conclusion as far as these numbers go. Four males were discharged better, aged respectively 33, 34, 35, and 52. Two males and one female, aged respectively 20, 50, and 26, were discharged no better, adding the case treated by myself. Out of eight we have four no better, being 50 per cent. of incurables.

TABLE.—Bath Mineral Water Hospital.—Statistical Results of Treatment of Disease, with Percentages.

When I contrast the percentage total (*vide* Table C) among males, and find that, under the comparative term "better", the percentage is 66.6, while under the positive term (if I may be a little ungrammatical) "no better" it is 33.3, I may be pardoned if I am somewhat sceptical of favourable results from this special treatment in this form of disease.

*Chorea*.—Sixteen cases of this disease were discharged from hospital during the year terminating May 1877. The records do not give any information as to their complications, or whether they were bilateral or unilateral. My own observations, founded on the cases which have been under my own care, would lead me to the conclusion that most of the cases have been bilateral, uncomplicated with cardiac or cerebro-spinal disease, though frequently associated with hysteria and sometimes with rheumatism. The table of statistics is a short one, as all the cases were under 20 and varied from 9 to 13 years of age. The small proportion of males to females is remarkable: three to thirteen. The percentage of results in this troublesome nervous affection is, I think, very favourable as regards those cured, amounting in females to 76.9 per cent. of females discharged, and in males to 66.6 per cent. of males total. The percentage of females cured in proportion to the total number discharged = 16 is 63.5, and the percentage of cured males and females collectively is seventy-five. The results of treatment of this affection by mineral tepid baths and waters was to me quite unexpected, and, had I not the opportunity of personal observation, I should have been sceptical. I can, however, vouch for the truth of these results as recorded on the patients leaving the hospital, nor have I remarked that choreic cases often apply for readmission. In those cases treated by myself, I have trusted entirely to the effect of the waters, and have not employed any supplementary treatment. It would be difficult to account for the *modus operandi* of the waters in cases of this disease. Of course, there is almost always functional cardiac disturbance.

[To be continued.]

## DEATHS FROM ETHER.

By CAWTLEY DAWSON, L.R.C.P., M.R.C.S., Leeds.

THE following analysis of the reports of deaths under ether is drawn up, not with the intention of comparing them with those under chloroform, it being assumed that the former has fully established itself as by far the safer anæsthetic, but with the object of gathering all the information they afford and learning, if possible, all the preventable dangers, so as to improve the results. If we are satisfied that, although the percentage of deaths from ether is apparently below that of deaths from chloroform, we can yet improve by experience, and help to raise still further, though in a small measure, the science of anæsthesia towards the high standard of perfect safety which we trust is its ultimate position, it is not enough that we read reports of fatal cases at the times they appear in our journals, but we must again and again recall them, place them side by side, compare them with one another, and so scrutinise their every feature with untiring zeal, that, if possible, we may trace certain marks running throughout them, and become so intimate with those marks as to be able to recognise their earliest appearance or prevent their appearance altogether.

In the BRITISH MEDICAL JOURNAL, *Lancet*, and *Medical Times and Gazette*, for the last ten years, there have been recorded one hundred and fifty-one deaths during the administration of anæsthetics. The following table shows the numbers recorded in each year.

In 1868 .. .. .	6 deaths.	In 1873 .. .. .	23 deaths.
" 1869 .. .. .	13 "	" 1874 .. .. .	11 "
" 1870 .. .. .	12 "	" 1875 .. .. .	16 "
" 1871 .. .. .	14 "	" 1876 .. .. .	13 "
" 1872 .. .. .	20 "	" 1877 .. .. .	13 "

For the mere purpose of statistics, these figures are perfectly useless because the journals have not been expected to be, nor have they claimed to be, authorities upon the numbers of deaths. Indeed, previously to the year 1872, there is abundant evidence to show that not only did they repeatedly speak of the deaths from anæsthetics without

reference to their number or individuality, but occasionally hint that many cases were allowed to pass away unnoticed or even unknown, except to those who were responsibly present. But about 1872, just previously to and especially after the time when our American brethren pressed ether upon our notice with strong recommendations, all three journals seemed to have commenced to enter into their pages, and even to solicit from all quarters, every individual record they could lay hold upon. Hence the apparent increase of fatal cases in the years 1872, 1873, etc., which, as was said at the time, must not be regarded as an evidence that such cases were increasing in number from carelessness on the part of the administrators, but is to be accounted for in the importance of recording them being more widely and more fully felt than ever. If, then, the deaths from anaesthetics have been more religiously recorded since 1872 for these general reasons, much more strictly would deaths under the administration of ether be reported for the additional reason of its being used *sub judice* by a cautious and almost sceptical profession. Still, even admitting that the above table includes, in the last five years, all or nearly all the deaths that have taken place in this country under the administration of ether, yet when we find them alone amounting to thirteen, though that number compares well with the number of deaths under chloroform, we feel that either we are not perfect in the art of its administration, or it is not the absolutely safe anaesthetic that we have been repeatedly told it is.

Let us examine the essential features of these thirteen deaths, together with five others that are reported in the same journals to have occurred in America, and compare the eighteen cases with each other.

1. A woman, aged 45, was to be operated upon for fatty tumour on the back, at the West London Hospital on February 18th, 1873. Chloroform was first given on lint, and, the pulse becoming irregular, ether was substituted. It became full and regular again, but suddenly stopped, the face at the same time being "dusky red". The ether used was pure; its specific gravity 700. One ounce of it was given. It was administered on a sponge in the apex of a cone made of felt, the sponge having been previously wrung out in warm water. The *post mortem* examination revealed nothing to account for death; all the organs were fairly healthy, except both lungs being gorged with blood.

2. An old patient had a cancerous submaxillary gland successfully removed under ether. Shortly afterwards, confusion and stupidity were observed, which deepened into unconsciousness with local convulsive seizures, and death supervened forty hours after the operation. The *post mortem* examination showed nothing to account for the mental symptoms. The chest was not examined.

3. S. S., aged 62, was to be operated upon at the Women's Hospital, in Birmingham, for ovarian tumour. After about five drachms of ether had been administered, she became satisfactorily unconscious, but suddenly appeared to revive, opening her eyes, and passing urine: the pupils were largely dilated, and the pulse could not be felt. Some subjective efforts at respiration were made, but they ceased, and Silvester's method of artificial respiration and other means of resuscitation were adopted without avail. At the *post mortem* examination, the cavities of the heart were found to contain a small quantity of dark blood. The other organs were healthy, except the ovaries and uterus. The state of the lungs is not reported. The anaesthetic used was a mixture of McFarlane and Co.'s anhydrous ether, and Heaton, Squire, and Frances' bichloride of methylene.

4. David Newman, aged 14, had iridectomy performed for corneitis. Ether was given in a cone of spongio-piline. Before the operation was commenced, alarming symptoms presented themselves—great struggling, opisthotonos, and feeble pulse. The administration of ether was discontinued; the pulse improved, and the operation was performed. Afterwards, the pulse and breathing stopped altogether, and the patient died. The *post mortem* examination showed the right cavities of the heart to be full of dark fluid blood, the left nearly empty; and the lungs were congested with bright red blood.

5. An old man was etherised by Mr. McGill of Leeds in 1873, and operated upon for hernia. Wild delirium set in afterwards; the patient tore off the dressings, opened the wound, and tore out some of his intestines.

6. J. F., aged 16, was etherised for operation upon diseased bone in the hand on April 3rd, 1875. Four drachms of Robbins's ether were poured upon some lint in a folded towel. The patient inhaled it rapidly, with no cough and with very little struggling. In four minutes, he was ready for operation, when respiration suddenly ceased, the face became pale, the pupils dilated, and the pulse imperceptible. At the *post mortem* examination, the heart was found not to be weak, and the lungs not congested.

7. On June 23rd, 1875, a man was placed under ether at the Cancer Hospital, London. He was thin and pallid, yet moderately healthy. Partial insensibility was first obtained by nitrous oxide; then ether, of the *British Pharmacopœia*, and specific gravity .735, was given in a cone of lint covered with oiled silk. After a slight struggle, the patient got under its influence. In five minutes, the face became dusky, the respiration shallow, a gurgling sound in the throat was heard, and an effort was made to expel blood. The pulse, however, remained remarkably good. Breathing ceased, though Silvester's method was tried: and still the pulse kept beating for some minutes. At the *post mortem* examination, the *general* blood was found dark, fluid, and containing bubbles like those of air. The lungs were fully inflated and grey. The right auricle was collapsed, and the ventricle empty; the left ventricle nearly so. A clot of blood was found in the trachea.

8. A patient at the Homœopathic College, New York, was etherised for operation upon a necrosed jaw. The pulse was watched all the time by another physician. The face suddenly became blue and the respiration ceased.

9. The *Chicago Medical Journal and Examiner* related a case of the Charitable Eye and Ear Infirmary in Illinois. A man aged 74 was operated upon for cataract by Dr. Holmes. The patient inhaled the ether quietly till half a pound had been used; when a violent coughing commenced, which was followed by extreme lividity of the face and cessation of breathing. The ether was discontinued, and, by appropriate means, respiration was re-established. The lividity partially disappeared, and the action of the heart became stronger. Without any more ether, the operation was concluded. Again the patient ceased to breathe. The face became more livid and the pulse very weak till death ensued, in spite of renewed efforts to avert it.

10. The *Boston Medical and Surgical Journal* gave the particulars of a case in which Dr. Sinclair incised the os uteri for dysmenorrhœa. The patient had been a teacher. She was operated upon at a private hospital on July 19th, 1876. The ether was given on a towel; and, when the patient became unconscious, the doctors present, wishing to be engaged with the operation, entrusted the continuance of the etherisation to a female. When they turned their attention again to the patient's condition, the breath and the pulse were found to have ceased. At the *post mortem* examination, engorgement of the pulmonary artery was found.

11. On September 15th, 1876, a man aged 28 had his right leg amputated for compound fracture, at Guy's Hospital, by Mr. Howse. The house-surgeon began with chloroform; and, when the patient was completely under its influence, substituted ether. After the operation was finished, and as the effects of the ether were passing off, retching came on, and the pulse became feeble. A little brandy was given. Almost immediately afterwards, the patient began to vomit and became blue in the face. A large piece of undigested meat was removed from the back of the mouth; still no air entered the lungs; other pieces of food were removed from the entrance to the larynx with no better results. Tracheotomy was performed, and artificial respiration and other means were attempted; but the patient died. At the *post mortem* examination, the larynx and trachea were found full of partially digested food.

12. The *American Journal of Medical Science* for October 1876 reported a case of death after ether. The patient, nineteen years old, had contracted chest and lungs seriously restricted by adhesions, which bound them down in all directions. The ether was administered for twenty minutes. Death followed about two hours afterwards. At the *post mortem* examination, bronchial mucus, pulmonary and pleural serous effusion were found.

13. The *Boston Medical and Surgical Journal* reported another case of death under ether. It was of an old woman in whom cerebral hemorrhage was afterwards found.

14. A man aged 69 was etherised by Clover's apparatus, for strangulated hernia, at the London Hospital. He commenced by inspiring only his own expired air for about thirty seconds; then he had the ether given in the proportion of from a quarter to a half for a minute. He struggled, and breathed the ether badly. The mouth-piece, therefore, was frequently removed from his face. The amount of ether was diminished, and, as his lips were blue, it was entirely discontinued. His breathing improved a little, but was not quite satisfactory. The pulse became weaker and weaker, and finally stopped; respiration, however, continuing for thirty seconds or more. At the *post mortem* examination, the heart was found flaccid, the left ventricle uncontracted, the lungs extremely emphysematous, the bronchi filled with mucopurulent matter, and other morbid changes were seen.

15. A patient, aged 56, had to be operated upon for a syphilitic caries of the leg at the East Suffolk Hospital. Bichloride of methylene was first administered; and, as the patient did not readily succumb,

methylated ether was substituted. The patient soon became unconscious; but, recovering unduly quickly, the bichloride of methylene was resumed. Great struggling and peculiar epileptiform convulsions ensued, followed by tonic spasm; this spasm relaxed; the breathing became stertorous; the pulse failed; and death supervened. There was no *post mortem* examination.

16. At the Moorfields Hospital, in August 1877, a very stout woman aged 46 was to be operated upon for cataract. A modification of Clover's apparatus was used. Forty minims of chloroform were added to the ether to prevent the choking sensation. The reporter of the case proceeds to say: "She had only breathed the mixture for one minute, when the face became livid, and could, therefore, hardly have been under the influence of the anæsthetic. The pulse and respiration continued fully four minutes after all anæsthetics had been discontinued." The anæsthetic had been applied on and off for some time after the first alarm. At the *post mortem* examination, the heart was found flaccid and empty; the mitral valve contracted; the walls in a state of fatty degeneration; the lungs emphysematous, and congested with blood.

17. Dr. Robert Saundby gave ether with Ormsby's inhaler to a case at Birmingham on October 4th, 1877. M. C., aged 35, had contracted knees. At 12.45 P.M., ether was commenced; only an ounce was used. There were no alarming incidents; very little stertor; no cyanosis; and the respirations were regular and full. Afterwards, the patient was carried out of the theatre across an open court for fifty yards, though well wrapped up. At 2.45 P.M., one hour and a half after leaving the theatre, the patient suddenly became alarmingly ill, cyanotic, and pulseless. Râles were heard over the chest. At 4.15 P.M., he died. At the *post mortem* examination, œdema was found in the membranes of the brain; no thrombus in the pulmonary artery; the heart was healthy, containing a little blood in the right auricle; the ventricles were contracted; the lungs were pale and œdematous; the other organs were healthy. The ether used was of the specific gravity 720.722.

18. At Lincoln, Miss S., aged 45, was etherised by Dr. Mitchinson for an operation upon a cancer of the breast. *Half-an-ounce of brandy was given first.* At three o'clock, pure sulphuric ether was administered by means of an inhaler, formed of a bag of muslin covered with a leather case, which had a valve at the apex and a larger one at the lower edge. The valves were open, and air was allowed free ingress and egress. Another doctor's finger was on the pulse of the patient all the time. Half-an-ounce having been poured into the inhaler, Dr. Mitchinson held it lightly over the patient's face. Immediately, she spoke as if half unconscious, and with two more inhalations became turgid about the face, and her hands pinched and white. There was no pulse. The tongue was dragged forward, and several forcible inspirations resulted. They, however, became less and less till 3.15, when she died. At the *post mortem* examination, the heart was found covered with fat; the right ventricle contained an ounce of fluid blood, the left was firmly contracted and empty; the muscular coat was one-twelfth of an inch thick. The base of the right lung contained a considerable quantity of fluid blood, and the base of the left a smaller quantity. There was cancerous deposit in both lungs.

Those of the above cases, which show, *primâ facie*, their causes and modes of death, may be at once taken out of the list, viz.:

No. 2, the old man, who, after the anæsthetic effects of ether had passed away, had not the strength to rally, but passed through the stages of confusion, stupor, unconsciousness, and coma successively within two days.

Nos. 3 and 15, the ether being in the one case mixed with, and in the other replaced by, bichloride of methylene.

No. 5, in which Robbins's ether was used; for Dr. Richardson says it is not pure ether, but a mixture of amyl hydride and anhydrous ether; it is useful in producing local anæsthesia by the spray-machine for which it is manufactured, being of a low boiling point and specific gravity; and it is directly dangerous when inhaled.

No. 11, in which the trachea was found filled with food.

Nos. 12 and 14, where previous pulmonary trouble was just aggravated by means of the ether.

Nine cases still remain, in which ether appeared to play no secondary part, nor even to be assisted by any untoward condition or circumstance; and the question immediately follows: What killed these patients? They who admit that, although ether is safer than chloroform, it is not absolutely safe, answer "asphyxia"; whilst all others, including those who assert the absolute safety of ether, give no answer at all.

It may be an advantage to draw up the essential particulars of these nine cases in a table, so that we may the more readily compare them altogether, and consider the following points.

- The important facts reported in these cases.
- The probable conclusions deduced from the facts.
- A theory explaining the facts and the deductions.
- The best method of the administration of ether.

Table of Nine Cases of Death under Ether.

No.	Kind of Ether.	Instrument used.	Quantity used.	First alarming Symptoms.	Time between commencement of alarm & death.
1	Pure; sp. gr. 720	Warmed sponge in felt cone	One ounce	Face dusky red; pulse stopped	Query? **
4	"	Spongio-piline cone	"	Opisthotonos, & pulse feeble	The operation performed in the interval
7	E.P.; sp. gr. 735	Lint cone covered with oiled silk	The inhalations during 5 minutes	Face dusky; respiration shallow; pulse good	Some length of time
8	"	"	"	Face blue; respiration ceased (pulse good)	Ditto ditto
9	"	"	"	Face livid; respiration ceased; pulse weak	The operation performed in the interval
10	"	Towel	1 lb. ss. on a towel; part lost in air	Face livid; respiration & pulse continued	Four minutes
12	"	Modified Ver's	Clô-inhalations during 1 minute	Face cyanotic; pulseless; râles	From 2.45 P.M. to 4.15 P.M.
17	Sp. gr. 720.2	Ormsby's inhaler	One ounce	Face cyanotic; pulseless; râles	From 2.45 P.M. to 4.15 P.M.
18	Sulphurised	Leather case with valves	Half an ounce, but only three inhalations	Face turgid; pulseless	From 3.0 P.M. to 3.15 P.M.

"Post Mortem" Appearances.

No.	The Lungs.	The Heart.	Other Organs.
1	Gorged with blood	"	"
4	Congested with bright red blood	Right side full of dark fluid blood; left side empty	All healthy
7	Trachea contained a clot of blood	Right auricle collapsed; ventricle empty; left nearly so	"
8	"	"	"
9	"	"	"
10	Pulmonary artery engorged	"	"
15	Emphysematous and congested	Flaccid; fatty walls; mitral valve contracted	"
17	Pale and œdematous	Right auricle contained a little blood	Healthy
18	Bases contained considerable quantity of blood	Right side contained one ounce of dark blood, left empty; walls a twelfth of an inch thick	Cancerous deposits

\*\* In the spaces of those cases where the double asterisks are placed, the reports gave no details to put in. Nos. 8 and 9 being shortly reported from American journals, many of their details are wanting.

A. *The important facts.*—They are easily recognised in looking over the table of the nine cases.

1. Ether was inhaled in various yet limited quantities, from three inhalations of it up to as many as would consume half-a-pound on a towel; and then produced the symptoms ending in death. It was diluted with various quantities of atmospheric air, and given in various methods.

2. The face was reported to be "dusky," "blue," "dusky red," "livid," "cyanotic," or "turgid" in seven of the nine cases, and never said to be "white" or "pale"; in the other two, the colour is not reported at all.

3. In seven cases, the heart did not cease till some time had expired after the commencement of the alarming symptoms, and after the ether had been discontinued; the intervals varying from four minutes to three hours. In those of which the notes were comprehensive, we read that the pulse remained feeble, weak, or good for a longer or shorter length of time after the ether had been discontinued, or after the alarm had been taken; in the other two cases, no certainty on that point can be gathered.

4. The lungs were reported to have been gorged with blood in five cases and the pulmonary artery in the sixth. In another, the trachea contained a clot of blood; and, of the remaining three, two cases were not reported at all; and one case only (No. 17), in which the patient died three hours after the ether-inhalation was over, were the lungs altogether "pale," and even then they were "œdematous."

B. *Two Deductions* seem to follow from these facts.

1. The fatal effects of ether do not depend upon any directly poisonous property of its own.

2. These cases died by "asphyxia".

Is not the former deduction indicated by the facts that the quantities

of ether given in these cases were various and often small, and the proportions of its mixture with air as well as the methods of its administration also various? And is it not further borne out by the experience of so many cases in which ether has been given in large quantities with the smallest possible amount of atmospheric air, and still the patients have to all appearances been perfectly safe?

Some cases might be quoted, such as those which caused men like Dr. Joy Jeffreys to affirm the belief of American surgery that ether is absolutely safe; but one will suffice. Mr. Furneaux Jordan related a case in which the ether was pushed to an extreme degree, on account of the marked and uncontrollable tremor of the muscles rendering the operation doubly difficult. The anaesthetiser, Mr. Priestley Smith, when requested by Mr. Jordan to give the patient more ether, remarked "that the man was as much under the influence of ether as it was possible to effect".

The second conclusion, that asphyxia was the mode of death, is, to my mind, irresistible from the dusky face, the shallow respiration, the interval between the commencement of the alarming symptoms and death, the engorged lungs, and other signs reported in most of the cases.

C. *A Theory explaining these facts and reconciling these conclusions.*—The intense cold produced by the ether under certain circumstances causes the small blood-vessels of the lungs to contract, and so offer such degree of resistance to the right ventricle of the heart as to stop it, if it be weak or wearied, and embarrass it, if it be strong; and, by watching the symptoms from this point of view, we are likely to be able to cope with the dangers as they may arise, or even (may we hope?) to prevent their occurrence entirely.

Assuming that the deductions under the head B are logically based upon known facts, we are driven into a corner out of which only such a theory as this can help us.

The asphyxia by which these deaths occur cannot be said to be brought on by any interference with the nerves or nerve-centres directly concerned in respiratory movements, *i.e.*, by paralysis of respiratory muscles, like the asphyxia from carbonic dioxide poisoning; nor, on the other hand, by any mechanical interference with the air-passages, as the asphyxia from hanging or drowning; but must be from interference with the chemical process of the aeration of the blood in the air-cells and blood-vessels surrounding them. This interference is not due to the want of oxygen, because *none* of these cases show that oxygen was absent; but most of them show the reverse, pure atmospheric air having been breathed for some time before death. It must, then, be the result of the insufficiency of the circulatory action of the blood in the capillary vessels of the lungs to do their share in carrying on respiration. What obstructs this circulation? It cannot be that the blood is poisoned with ether; for, in one case (No. 18), three inhalations only had been taken, and, in another (No. 16), the ether had been administered for one minute only. It must be from some property of ether which comes into action in certain circumstances; and, when we call to mind its power of producing intense cold under some conditions, we venture to inquire into the likelihood of that property being the cause of asphyxia. Suppose it to be true. Ether, in its administration, becomes a vapour by absorbing a fixed amount of heat from surrounding media, generally the atmosphere, and, in that condition, is inhaled into the larger bronchial tubes and then becomes mixed with the residual air in the smaller tubes and alveolar spaces. From them it is absorbed into, and dissolved by, the blood, becoming a fluid again virtually in that act, and therefore giving off a certain amount of latent heat. This heat diffuses itself through the body as well as the ether, and probably much faster, the latter having to be pushed on to other parts by the continued addition of more ether behind. This process goes on as long as ether is added. When its administration is discontinued or interrupted for any reason, and pure air allowed to enter the lungs, the current of osmosis between the blood in the capillaries of the lungs and the contents of the air-cells is reversed. The ether, having now to change from the state of fluid to that of vapour again, reabsorbs the amount of heat it gave off on its entrance into the blood. If the air which has just entered the lungs be warm, the abstraction of heat for the re-evaporation of the ether will not be felt by the lungs, though it is sudden and local; but, if, on the other hand, that fresh air be cold, whether on account of its passing through or close to an ice-cold instrument, rendered so by the action of the ether, or from the room being cold, or from the patient having been put into a cold place, though well wrapped up, the amount of heat required suddenly by the ether on its returning to the atmosphere will be more; and the lung-tissue, not having stored up the heat, the ether brought to it will, upon this sudden demand, become so cold as to cause a violent contraction of its arterioles. Such an amount of obstruction, from this

contraction of a large number of vessels, without anastomoses or diverticula, resists the right side of the heart; that, unless the latter has an immense margin of strength, failure in its function is the result, and the patient dies in a space of time varying with the amount of resistance and the amount of strength the right ventricle possesses. If the death were rapid, there would be engorgement of the main branches of the pulmonary artery and the right side of the heart. But the heart may be able to overcome this obstruction; then the capillaries of the lungs become engorged, the chemical process in respiration becomes impeded, and the *vis à fronte* more or less lost. Here is another and, perhaps, greater resistance to the heart, and the latter, wearied out now, might fail. In this case, death would be more delayed than in the former; the pulse might be felt to become more and more feeble. Afterwards the lungs would be found engorged with blood, and the right side of the heart might be full of dark blood or the reverse.

But a strong heart might be supposed to overcome even this second resistance; then the engorged capillaries would throw out a quantity of serum into the air-cells and the surrounding tissues; that in the air-cells becoming frothy and being expectorated; that in the tissues, perhaps, after some time becoming reabsorbed, or possibly causing so much difficulty in the acts of respiration as to constitute the last straw and break the camel's back by offering such embarrassment to the exhausted heart that the patient at last succumbs.

D. *The Best Method of the Administration of Ether.*—My own experience consists principally in having administered anaesthetics for Mr. Pridgin Teale's cases in private, with very few exceptions, during the last year and a half. In those cases, except with very young children, ether has nearly always been administered. At first, we used the sponge, covered with mackintosh; then the American framework, with the bandage weaved in it; next, Clover's larger apparatus; lastly, Clover's smaller and more recent inhaler. I have also used Ormsby's inhaler a few times.

In my opinion, Clover's smaller inhaler is the best. It is made by Meyer and Meltzer, Great Portland Street. It is composed of an ether chamber and water chamber, together in a circular vessel, a bag that can be detached, and a face piece, which likewise can be detached, and which rotates, when fixed to the vessel, for the purpose of regulating the amount of ether-vapour. It has no valves, or sponge; and costs between £3 and £4.

It possesses the following advantages.

1. There is no struggling or resistance on the part of the patient, however terrified or prejudiced he may be; the ether being invariably breathed with comfort, and in many cases with even a sense of pleasure.
2. The amount of ether-vapour can be carefully regulated to a nicety without lifting the machine from the patient's face, and, consequently, it is easy to keep a patient on the very borderland of insensibility for any length of time.
3. The ether being economised, and not being dissipated into the surrounding atmosphere, there is not only a better chance of fresh air if needed for the patient, but there is more comfort to the operator and his assistants, and especially to the anaesthetiser, who, with other contrivances, often inhales a large share of the vapour himself, and in consequence suffers many a headache. There is also a considerable saving of ether; an ounce and a half usually being sufficient for half an hour, when formerly eight, nine, or more ounces were used.
4. There is none of that bronchial mucus which gave, with other instruments, so much trouble at the time of inhalation, and which was often followed by bronchitis, and in some instances by death.
5. When consciousness has so far returned that the patient can recognise, and even speak sensibly, the sensibility to pain is still so numb that an operation may be concluded, sutures put in, and dressings applied, without the slightest sign of pain from the patient.
6. The comfort to the patient, silencing his resistance and calming his mind, the ease with which the anaesthetiser can administer and regulate the ether without the distraction caused by the patient's struggles, or the etherised atmosphere, or the repeated application to an ether-bottle for fresh supplies, and the equable temperature at which the ether-vapour can be kept, combine together to ensure the greater safety to the patient.

The following are the details of the method of administering ether with the abovementioned machine which I have adopted, keeping in view and acting upon the theory spoken of under the division C of this paper; and Mr. Teale expresses himself well satisfied with the practical results that continue uninterrupted under his observation.

1. Never allow any solid food, milk, or spirits to enter the patient's stomach for six hours beforehand.
2. See that the room is well warmed.
3. Detach the bag and face-piece from the metal vessel of the

machine; warm the vessel by placing it in a basin of hot water an inch deep; pour an ounce and a half of methylated ether, specific gravity 714, into the ether-chamber; put the face-piece to the vessel, and rotate it so that the indicator points to "no ether". Let the patient breathe through the vessel without the bag into the air, so that he gets only a flavour of the ether; his nervousness and fear will by this means be soon allayed, and confidence gained. Avoid giving him the choking sensation until he becomes numb to the ether; by giving him the ether slowly at first, imperceptibly and gradually increasing it, the bag being placed to the vessel, and so stealing over his sensitiveness until he is quite "numb". Then proceed rapidly to full ether, without any atmospheric air; watch the respiration closely. If it be at all embarrassed, give one breath of fresh air, and resume the ether, at first weak, but increase it as before. He will soon be under its influence; then reduce the proportion of ether by the regulator, so as to keep him just beyond the boundary line of sensibility; give him one breath of fresh air occasionally. Continue to watch the respirations closely. After the operation, do not place the patient suddenly into a cold room or passage, even if he be warmly clothed.

## CLINICAL MEMORANDA.

### APPARENT GLYCOSURIA AS A RESULT OF THE ADMINISTRATION OF SALICYLIC ACID.

WHEN visiting a case of acute rheumatism in Guy's Hospital, which I was treating with salicylate of soda, I was told that that morning the urine (which was free from sugar on admission) gave a distinct reaction with copper. Next time I examined it myself, and found a more abundant precipitate. The specific gravity was somewhat high, but the quantity was not increased, and there were no other symptoms of diabetes. The reaction disappeared after a few days, when the drug was given less frequently; and, though a slight relapse led to its being again administered every two hours, the presence of sugar was not again noted.

A few days later, another patient taking salicylate of soda for rheumatism was found to have a trace of sugar in his urine. I then suspected its source, and the ward-clerk, Mr. Charles Wood, undertook to examine the urine of all the patients in the hospital who happened to be taking salicylic acid in the form of the soda or ammonia salt. In sixteen out of eighteen cases, the copper was reduced. I have myself tested the urine in other patients for whom I had prescribed salicin or salicylates for rheumatism, urticaria, or common colds, and have never failed to find more or less reaction with the copper-test. The specific gravity was usually not raised, and there was no polyuria or other symptom of diabetes. The reaction disappeared when the drug was no longer taken, and its effect was the same in healthy persons.

An alkaline salicylate is probably decomposed in the circulation into the corresponding carbonate and nascent salicylic acid, and this is partly or entirely excreted in the urine in the form of salicyluric acid. Salicin, it is well known, is excreted as salicyl hydride. Since excess of uric acid will itself reduce copper salts like grape-sugar, and it is possible that salicyluric acid is the reducing agent, salicin, heated with dilute mineral acids, takes up water and forms saligenin and glyucose; and I find that, whereas salicylic acid and salicin have no reducing action on copper in an alkaline solution, they exert it when previously acidulated with acetic or mineral acids or when added to acid urine.

I hope to pursue the inquiry further, but thought it well, in this preliminary communication, to call attention to the fact, as one of clinical interest, that the ordinary test for sugar in the urine acts as I have described in persons taking salicylic acid, whether this be due to glycosuria or some other cause. I may add that in every case perchloride of iron produced its characteristic reaction in the urine.

P. II. PYE-SMITH, M.D.

### NOTES ON A CASE OF SEVERE INFANTILE CONVULSIONS.

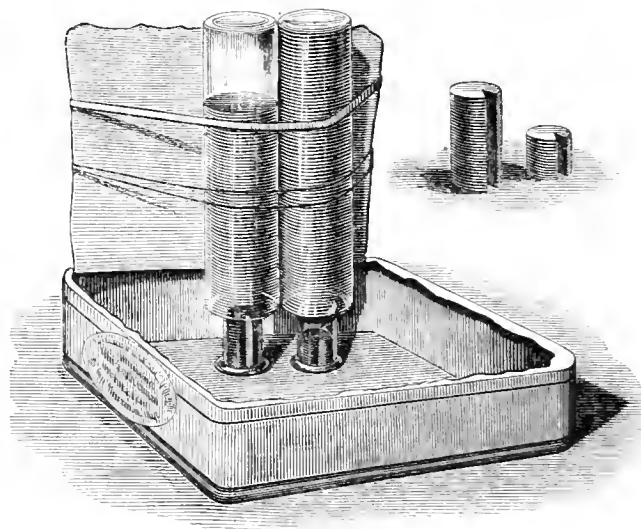

ON February 2nd, I was called in to see an infant twelve days old, and that weighed six pounds two days after birth. She was suddenly seized with violent contraction of nearly every muscle in her body, the head being violently jerked backwards and forwards; the face was alternately red and livid; respiration was very irregular and laborious; the features were fearfully distorted; and there was involuntary discharge of feces and urine. These symptoms had gone on more or less for three hours without a decided intermission. On endeavouring to

find a cause, I could not. The bowels had acted regularly up to the attack; the remains of the umbilical cord were normal; the appetite was not impaired; and the child had had nothing but her mother's milk since birth. The sister died from convulsions when about twelve months old. I ordered the usual remedies, such as cold to the head, the feet to be placed in hot mustard and water, etc.; but they were of no avail, the symptoms being as persistent as before. I gave the infant an inhalation of equal parts of chloroform and ether, producing complete insensibility, which I kept up for twenty-five minutes, the chaplain christening the child during the administration of the anæsthetic. The inhalation being discontinued, the convulsions were replaced by apparently a sound natural sleep, lasting upwards of three hours and a half, after which some slight muscular twitchings were observed. I then administered two grains of chloral-hydrate, which had the desired soporific effect. The infant awoke up bright and cheerful, without a sign or symptom of muscular twitching, and has remained in perfect health up to the present time.

JOHN R. PARKINSON, M.R.C.S.,  
Lancashire County Asylum, Whittingham.

### THE DETECTION OF SUGAR IN URINE.

THE employment of the fermentation-test for the detection of sugar in the urine is, I am afraid, not so frequently used as it should be. This arises from some little difficulty in the manipulation. To obviate this, I have devised a simple and inexpensive apparatus, which is very easy to use, and gives trustworthy results. It consists of a couple of ounce-and-a-half vials, with their corks, and an empty used sardine tin. The lid of the tin is bent at right angles with its cavity, and affords a support to the two vials, an elastic band or two being used to retain

them in their proper vertical position, while the cavity of the tin receives a portion of the urine under examination sufficient to cover the inverted ends of the bottles, thus forming an extemporaneous pneumatic trough, allowing the whole concern to be put in any situation where the required temperature can be maintained. The vials are two of the ordinary "long series" ounce-and-a-half size. The corks are of unequal length, and each has a triangular notch, about one-twelfth of an inch deep, cut through the entire length of one of its sides. This constitutes the whole of the mechanism. In using, the bottles are to be filled to the very brim with the suspected urine. To the vial which takes the longer cork, a little yeast is to be added; the cork is then forced in level with the neck of the bottle. The notch in the cork allows the superfluous urine to escape. The bottle can then be inverted without a particle of air entering, and placed mouth downwards in the stratum of urine contained in the hollow of the tin. The other bottle is to be treated in the same way; but no yeast is to be put in it, and it is to be placed side by side with the other. The bottle containing the yeast is recognised by its longer cork; and if sugar be present, at a sufficient temperature fermentation soon commences. Gas is evolved, and is retained in the upper part of the bottle, while an equal bulk of urine is expelled through the slit in the cork. The bottle with the shorter cork having no ferment added to its contents, remains full and

unaffected, affording a striking means of comparison. By always using the longer cork for the bottle to which the yeast is added, no mistake can occur. The whole affair, being bound together by the elastic bands, can be safely carried about and exposed to the requisite temperature. The thing is thus done as easily as the copper or other tests. A little modification would afford a quantitative result.

THOMAS BIRT, M.D., Leamington.

## THERAPEUTIC MEMORANDA.

### IODOFORM AS A LOCAL APPLICATION IN VENEREAL SORES.

THE therapeutic use of iodoform having been brought to the notice of the readers of the BRITISH MEDICAL JOURNAL of January 26th, by Mr. Berkeley Hill, and its value in venereal sores therein demonstrated, I should like to state that, in my limited experience at the Liverpool Seamen's Dispensary, I have seen very beneficial results follow its application to indolent non-specific sores. In the case of an obstinate ulcer of the frænum, which defied treatment for weeks, I applied the ethereal solution of iodoform. In three or four days, the change for the better was marked. The sore healed in less than a fortnight. In another case of extensive indolent ulceration of the body of the penis, occupying nearly its circumference, and upwards of an inch in width, I applied a similar solution. The result could not have been more satisfactory. The sore healed in about fourteen days. I have used it on two or three occasions in open buboes, where sinuses had formed, with the same satisfactory results.

Outside my own practice, I have also seen its value fully proved; and Mr. McCheane, Senior Surgeon to the Liverpool Lock Hospital, who uses it extensively, has told me that, in his hands, it has proved invaluable. Its beneficial action appears to consist in its antiseptic and absorbent properties, and in its also acting as a stimulant. The smarting which accompanies the application of the ethereal solution seems variable; being in some cases sharp enough, to judge from exclamations on the part of the patient; in others, inappreciable. The odour certainly is disagreeable, which is unfortunate, as possibly it may deter sensitive patients from submitting to its use.

I cannot conclude these few remarks without expressing the satisfaction afforded me in reading the interesting article by Mr. Wyndham Cottle, on the same subject, in the number of the BRITISH MEDICAL JOURNAL for February 9th.

ARMAND BERNARD, B.A., M.B.,

Surgeon to the Liverpool Seamen's Dispensary.

### ON THE LOCAL USE OF IODOFORM IN EAR-DISEASES.

THE following are the conclusions to which I have come, after using this agent in the treatment of ear-diseases during the last two years.

Iodoform is of service alone in cases of ear-disease in which there is a lesion of tissue (ulceration), and notably in those of caries of the mastoid, complicated with polypous granulations. After these are removed, the local application of iodoform, as a fine dry powder, generally acts capitally and, I may add, successfully. I intend, however, to give it a trial as an internal remedy, not with much hope of success resulting, I confess, in those cases of deafness following eye-disease, having keratitis and scooped (Hutchinson's) teeth, and other outward signs of hereditary syphilis.

JAMES PATTERSON CASSELLS, M.D.,

Aural Surgeon to the Glasgow Royal Infirmary.

### OPIUM AND ATROPINE.

THE record of Dr. Fothergill's case in last week's JOURNAL suggests the publication of a case which occurred under my observation recently. I have always desired the house-physician acting under me to make use of atropine in severe opium-poisoning; and Mr. Spofforth, with other residents, carried out the treatment judiciously and successfully, as will be seen. [The case is described at page 297.]

There is not quite the same point as in Dr. Fothergill's case, viz., the use of a lethal dose of atropia without sign of lethal action, but still a fairly large dose (about one-seventh of a grain) was given without other marked effect than dilating the pupils, unless it were "dancing a jig". We could have wished for a note as to temperature and change in respiration, but, in the urgency of the case, these were omitted.

*A propos*, I am now attending a nervous patient, who is extremely

susceptible to the action of atropia, and who passed into a state of uncontrollable excitement after the application of belladonna-extract to about six inches of his skin. His wild excitement and restlessness and pain in the head were amended in a few seconds by one-eighth of a grain of morphia injected hypodermically, and the widely dilated pupils soon passed into the opposite condition.

The following also is instructive. To obviate the depressing effects produced in this patient by even small doses of morphia, I adopted the now usual combination with atropia, giving one-fifth of a grain of the former with one-hundredth of a grain of the latter. The solutions were in separate bottles, and I took up in the needle first the morphia and then the atropia solution, so that the latter was nearer to the point of the needle. Allowing a few seconds for their mixture, I injected into the arm as usual. The patient was calmed from a state of excitement and gastric pain, and went to sleep. Fifteen minutes afterwards, he woke with throbbing in the head, jumped from bed, and passed into the state of excitement which I had before seen in him from the belladonna extract. He said he felt as if dying; but I noticed no great change in respiration, the pulse was quickened, and the pupils were widely dilated. I gave him five drops of nupenthe, and in about half-an-hour the excitement subsided; and when I saw him next, two or three hours afterwards, the pupils were contracted, and he remained pleasantly under the influence of morphia during the next day, sleeping it off quietly the next night.

This first action of the first alkaloid injected is curious. I presume that atropia circulates somewhat more quickly than the other; but it is worth while to mix the solution well before use.

EDWARD MACKEY, M.D., Brighton.

### TREATMENT OF BURNS AND SCALDS BY CARBONATE OF SODA.

I HAVE used bicarbonate of soda for some years past; at first in minor burns and scalds of a domestic kind, and afterwards in pit, foundry, and gas explosion burns. I use only the washing soda of commerce. It is kept in the surgery ready. If called to an accident where two or more are injured, I put a pound in a wash-hand basin and fill with water; thin soft cloths in small pieces are dipped in the solution and laid over the parts, and covered with dry flannel. A dose of solution of morphia is given if the injury be severe. The cloths may be rewetted two or three times when dry. The pain is intense for from a few minutes to half an hour, according to the extent and nature of the injury. After that, there is no pain; and, should the tissues have been much injured, the sores remaining readily heal under bread and milk poultices, or a mild ointment or lotion. Some curious episodes have arisen from its use. After undergoing all the terror and pain of a severe burn, the sufferer perhaps next day has nothing to show, and has been looked on as an impostor making much ado about nothing. In December 1876, an ironmoulder tripped and fell while carrying a pot of metal. His right arm was immersed in the molten mass before he could get to his feet, and the arm was much burnt and charred. The soda solution was applied early, and, if I remember right, he was at work in a fortnight. In September last, a number of men of our fire brigade were burnt, some of them severely, by an explosion of gas at a fire. My assistant and myself were early at the place, and covered them all with the soda solution. One, a soldier who was assisting, was sent to the Military Hospital; and another, who felt and appeared to be much injured, insisted on being sent to the Western Hospital. Only one of those under my care was confined to the house for a few days, and all were able for their duties in ten or twelve days.

WILLIAM McDONALD, L.R.C.P., L.R.C.S.E.,

Medical Officer to the Glasgow Plate-Glass Company, etc.

## PATHOLOGICAL MEMORANDA.

### NOTE ON THE HARDENING AND PRESERVATION OF PATHOLOGICAL SPECIMENS.

AFTER many experiments with different fluids, I have as yet found no better fluid for the purpose of hardening and preserving museum specimens than a strong alcoholic solution of carbolic acid and creasote.

The carbolic acid should be dissolved in a little spirit, and the creasote then added: a clear solution results, which is not altered by the subsequent addition of the methylated spirit; and the following proportions are recommended for the purpose: Creasote, 1 part; carbolic acid, 1 part; methylated spirit, 38 parts. The hardening of lung-tissue, with which I am chiefly concerned, is not easily effected by

alcohol alone, and mucous tissue and fluid loses a large quantity of water before hardening; but, with the above fluid, the larynx is very rapidly hardened, and tubercle, which completely alters its macroscopical appearance in alcohol, is better shown after immersion in this fluid than in any other that I have yet tried: the colouring matter of the blood is but little altered by it, and may be thus preserved for some time.

For putting up specimens, glasses, with a glass cover ground at the edges to fit close, are well suited. These are often glued together with shoemakers' glue; but, as there is much risk from the heating of this substance, and as the glue is soluble in spirit, I have altogether discarded this method and use diamond cement. This is solution of gelatin in acetic acid, which is readily softened by the application of hot water, is easily applied by a brush, and is quite insoluble in spirit.

REGINALD E. THOMPSON, M.D.

## OBSTETRIC MEMORANDA.

### TURPENTINE IN POST PARTUM HÆMORRHAGE.

I HAVE long been in the habit of giving turpentine in half-ounce doses in cases of *post partum* hæmorrhage, and I can fully corroborate the favourable testimony of Mr. Pollard of Torquay in the JOURNAL of February 23rd. Turpentine, however, has this disadvantage, that it is very likely to be rejected by vomiting; and it cannot be used hypodermically like ergotine. Mr. Pollard states that he does not remember to have seen large doses of turpentine ever advocated. If he will refer to my *Obstetric Aphorisms*, he will find that it is recommended even in the first edition of that work, which appeared in 1856.

JOSEPH GRIFFITHS SWAYNE, M.D., Clifton.

MR. JAMES POLLARD will find the value of turpentine in menorrhagia admitted at page 238 of my *Handbook of Uterine Therapeutics*; and at page 409 he will see that ten years ago Mr. Bradley of Martley recommended half-an-ounce of turpentine in milk to cure *post partum* flooding. It is best to prescribe "fir-oil" instead of the ordinary turpentine.

EDWARD J. TILT, Seymour Street.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

#### EVELINA HOSPITAL FOR SICK CHILDREN.

##### THREE CASES OF CEREBRAL DISEASE.

(Under the care of Dr. E. BUCHANAN RANTER.)

**CASE I.** *Cerebral Fever ending in Death: Optic Neuritis an early Symptom: Meningeal Tuberculosis without Meningitis.* (From notes by Mr. HAYWARD.) Jane S., aged 9, entered the hospital on October 19th, 1877. Three months before her admission, she used to suffer from pain in the back and occasional headache. She was sent into the country for a few weeks, and returned in good health. On October 12th, she complained of severe pain in the lower part of the back and in the shoulders on getting out of bed; soon afterwards, her head began to ache and she vomited. She had been sick once or twice a day ever since. The vomiting took place quite suddenly about thirty minutes after a meal; the food was thrown up without retching or straining. She had not taken to her bed, though during the last two days she had been very drowsy. Her sleep was disturbed; she dozed a little and then woke up with a start, complaining of her back or her head. The bowels were confined. The appetite was pretty good. She had had measles, whooping-cough, and small-pox.

On admission, she was well-nourished, of fair complexion, with flushed cheeks. She lay on her back, with her legs drawn up. Her chief complaint was of pain in the back, and occasionally in the head also. She objected to put her legs down in the bed, saying that this hurt her back. Though her manner was rather listless, she answered questions readily and to the point. Respirations were tranquil, regular, 18; pulse 56, feeble, slightly irregular in rhythm. Temperature normal. The tongue was moist, thinly furred. The heart, lungs, and urine were normal. Cerebral macule were well marked on the somewhat flattened abdomen and on the forehead. There was a slight inward squint of the

left eye; but this was probably of old standing. The pupils were equal, sensitive to light; vision was apparently good. On examining her eyes with the ophthalmoscope, both optic discs were seen to be of a dull buff colour, woolly, with blurred edges; the veins were tortuous and distended; the arteries masked at intervals. There was no retinal hæmorrhage; no tubercles in the choroid. During the next three days, she was alternately restless and drowsy, but did not vomit. On the 23rd, she was delirious and almost maniacal. On the 24th, she was comatose, with equally dilated pupils, and began to pass her evacuations under her. On the 25th, her temperature, which had not previously risen above 100 deg. Fahr., shot up suddenly to 103.2 deg.; her abdomen fell in; her eyeballs were noticed to be oscillating continually and independently of each other. On the 26th, she was still insensible, breathing 46 per minute, with a fluttering pulse of 208. She died the same evening without ever having manifested paralysis, rigidity, or convulsion.

**Treatment.**—An attempt was made to bring her quickly under the influence of mercury by rubbing in grey ointment. This was begun on the 22nd; it exerted no appreciable influence on the course of the symptoms; neither was it followed by its usual physiological effects.

**Post Mortem Examination.**—A few hemp-seed-like tubercles were found in the pia mater, lining both sides of the longitudinal fissure, on the upper surface of the cerebellum, and on the tip of the right middle cerebral lobe. There may have been a dozen and a half of these bodies altogether. The pia mater in their neighbourhood showed no trace of inflammation. None were found in the Sylvian fissure or elsewhere; there was a complete absence of lymph or other inflammatory products at the base of the brain. There was no excess of fluid in the ventricles; the brain-tissue looked perfectly healthy to the naked eye, and was nowhere softened. The lungs were much congested and almost carnified at their base, but they contained no tubercle; neither was any found on the pleura or peritoneum. No cheesy mass was detected in any part of the body; the only trace of old disease being a partial adhesion of the right pleura. When the tubercles were subjected to microscopic examination, they were found to be cheesy and granular throughout, retaining no sign of their original corpuscular structure.

**REMARKS.**—The value of the routine use of the ophthalmoscope, much insisted on by Dr. Hughlings Jackson, is well illustrated by this case. At a stage of the malady, when objective symptoms were few and insignificant, the existence of optic neuritis at once disclosed the true nature of a case whose exceeding gravity might otherwise have escaped recognition for days. Yet there was nothing to call attention to intraocular mischief. Another point of interest is the striking disparity between the violence of the disease during life, running a precipitate course to its fatal issue, and the relatively trifling changes found in the brain, or rather upon it, after death. All the structural lesions commonly met with in tubercular meningitis might reasonably have been looked for; yet they were all conspicuous by their absence. Indeed, it might fairly be argued that the obsolete tubercles in the pia mater had no very immediate connection with the disturbances preceding the patient's death. It is far from easy to construct any rational hypothesis which will account for a few minute foreign bodies on the surface of the brain causing such profound disorder of essential functions. It is easier to take refuge in the belief that the visible minimum of structural damage represents a maximum invisible to ordinary inspection. This belief, however, comes more readily to those who read the account of a *post mortem* examination than to those who make it.

**CASE II.** *Persistent Retraction of Head: Screaming and Restlessness: Occasional Vomiting: Absence of Optic Neuritis: Simple Internal Hydrocephalus.* (From notes by Mr. BOTT.) Thomas W., aged 2, supposed to be in good health, had a fit of some sort, lasting about an hour, on December 10th, 1877. Since then, he had been drowsy, and unable to stand without support (he used previously to run about without help). His head had been constantly retracted, and he screamed when he was moved. Before the attack, he was able to speak a few words; he could not now be induced to say anything. He had never had any illness except thrush, which he had severely. He cut his teeth and began to walk early. His mother had had four other children, all alive and well. The present boy was one of twins; the other, a girl, was in excellent health. There was no history of injury to the head.

On admission (December 20th), he was a well-nourished rosy child, lying on his back with his head drawn back as far as it would go. The muscles at the back of the neck were rigidly contracted; any attempt to bend the head forward into a line with the rest of the body was strenuously resisted by the patient, who screamed lustily when he was touched. His screams were more like those of a bad-tempered or passionate child than of one in pain. The persistent retraction of the head, together with restlessness and unwillingness to be touched, was really all that could be made out. The temperature was below the normal;

breathing quiet; pulse quick, but regular. There was no apparent weakness or rigidity of the limbs; no vomiting; no squint. The pupils were equal. There was no vomiting or constipation. The belly was neither tumid nor drawn in. There was no trace of old rickets or of syphilis.

Up to December 29th, there was no change in the symptoms. His restlessness at night was so great that small doses of chloral-hydrate had to be given to procure sleep, which they effectually did. From this time forward, he began to vomit occasionally, and his eyeballs were frequently noticed to converge. They no longer followed a bright object moved before them. Still, he was not blind; for, if the finger were suddenly brought near the eye, he would close it. On December 31st, his pulse was noticed, for the first time, to be somewhat irregular in rhythm. On January 11th, he screamed frequently, even when he was not disturbed; when any attempt was made to raise him up, he arched his back and dug his head and heels into the bed, screaming violently. His nutrition had not hitherto suffered; he was neither wasted nor anæmic. January 28th. For the past week, he had vomited nearly everything he had taken; he now looked, for the first time, pale and ill. He slept more than he did by day; hardly at all by night, unless chloral had been given. The pupils were dilated, equal. He now moved his head from side to side occasionally, though it continued retracted as far as ever. On January 30th, he died quite suddenly and almost unexpectedly; he had ceased to be sick for a couple of days before his death, which was not preceded by any convulsion. At no time during his sojourn in the ward did the rigid spasm of the muscles at the back of the neck abate. His eyes were repeatedly examined with the ophthalmoscope, and the discs were always found normal. He took three-grain doses of potassic iodide thrice a day till January 25th; they did not produce any appreciable effect on his symptoms.

*Post Mortem Examination.*—On removing the skull-cap, the convolutions were seen to be flattened, the sulci effaced; the veins of the pia mater over the vertex were turgid with black blood. When the anterior lobes of the brain were drawn back out of their bed, the third ventricle was seen forming a cyst-like expansion, over which the optic nerves were stretched. When the infundibulum was torn across, several ounces of clear liquid escaped from the ventricles. The anterior fontanelle was slightly patent; the sutures were solidly united; the vault of the cranium was thinned in patches; the orbital plates of the frontal bone were not depressed. There seemed to be an unusual amount of connective tissue over the cerebro-spinal foramen; but it was not possible to determine, with any certainty, that it had been impervious. The ventricles of the brain had all been greatly stretched by the accumulated fluid in their interior; the *iter a tertio ad quartum ventriculum* and the foramen of Monro were much dilated. There was no tumour, no trace of tubercle, no sign of inflammation or softening, in any part of the brain or its membranes. The lungs were pale, emphysematous at their edges, otherwise normal. The heart's cavities were distended with fluid blood, their muscular walls relaxed. Nothing abnormal was noticed in the abdominal viscera.

*REMARKS.*—The nature of the mischief in this case was not recognised during life. Putting the chronic hydrocephalus of infancy aside, intraventricular effusions in children are usually secondary to tumours in the hinder portion of the brain. These are supposed to cause passive dropsy by pressing on the veins of Galen—a hypothesis the truth of which, in the majority of cases, it is difficult either to confirm or to disprove. In the present instance, there was no tumour; and the sole cause to which the dropsy could be referred was a possible occlusion of the cerebro-spinal opening. Intraventricular hydrocephalus, setting in after consolidation of the sutures, is extremely difficult of recognition. The head may be peculiar in size or shape. Careful examination may sometimes disclose slight mobility of the parietal bones upon each other along the line of the sagittal suture, and the anterior fontanelle may remain slightly open long after it ought to have closed up. The absence of rickets must, of course, be established. Ricketty heads are often erroneously taken to be hydrocephalic. In a ricketty child, there is no certainty of intraventricular effusion unless the orbital plates of the frontal are visibly depressed; but this sign is never present in the cases now referred to. Apathy, alternating with restlessness when roused; extreme dislike to change of posture—from the horizontal to the vertical and *vice versa*—a change which seems to cause disagreeable sensations, occasionally amounting to severe pain, probably by suddenly altering the blood-pressure within the cranium—the alteration not being susceptible of compensation owing to the damming-up of the cerebro-spinal fluid; rigidity, permanent or paroxysmal, of the muscles at the back of the neck; these are among the best corroborative symptoms, though they are not individually distinctive. Widely dilated pupils are sometimes mentioned in this connection, but they are seldom observed till a very late period of the disease.

*CASE III. Solitary Tubercles in the Brain: Intraventricular Hydrocephalus: Death from Basilar Meningitis.* (From notes by Mr. S. ANDREWS.) William M., aged 2½, was in his usual health on April 8th, 1877. On the evening of the 9th, his mother noticed that his mouth was drawn, his left eyelid drooped, and that he took his food with his left hand instead of his right. He had been running about as usual that afternoon, had met with no accident, and had made no complaint. In a few days' time, he began to limp, and was found unable to raise his right hand without the aid of its fellow. He became rather fretful and slept less tranquilly than usual. There was nothing in the way of a convulsive attack, vomiting, or other general disturbance. He was the sixth child in a large family, the history of whose members threw no light upon the case.

On admission (April 17th), he was a well-nourished healthy-looking boy, displaying an unusual degree of intellectual quickness. All the branches of the left third nerve were completely paralysed, with the exception of those supplying the sphincter fibres of the iris through the lenticular ganglion. When the fallen lid was raised, the eyeball was seen to roll outwards; but the pupil was of the same size as its fellow, and acted with equal readiness under the influence of light. The right arm and leg were decidedly weak. He could support his weight on the leg when he was set up; he could grasp any object put into his hand; but he would not stand up without help, and never used the right hand of his own accord, generally keeping it hidden up his sleeve. The right arm and leg were always colder than the left. When he smiled, the mouth was drawn slightly over to the right side; there was no other evidence of facial palsy, no rigidity of any of the muscles. He ate and slept well; was full of fun and almost morbidly shrewd. Temperature normal; pulse regular.

On April 23rd, iodide of potassium, in three-grains, was ordered three times a day. He continued to take it till May 17th.

On June 12th, it was noted that he had gained some power over the left eyelid and the right hand. The muscles of the arm were slightly rigid. The optic discs were examined and found normal.

In the latter part of June, he had a mild attack of measles, unattended by any complications. This illness had no appreciable effect on the paralysis.

July 13th. Since the measles, he had lain in an apathetic condition, which contrasted strikingly with the restless buoyancy he showed before. His evacuations passed under him. No signs of acute cerebral disturbance were present.

July 16th. He was feverish; the temperature fluctuated between 99 deg. and 101 deg.; pulse 120; breathing 48. He had no appetite. He took hardly any notice when spoken to; when raised up in bed, he cried, as if in pain. An attempt to lift him up this morning brought on a slight epileptiform paroxysm; the pupils were dilated, the eyes fixed; there was slight twitching of the right arm and leg, lasting a few seconds only, and followed by momentary rigidity. A minute later, the muscles were again relaxed; the cerebral macula was faintly brought out on the forehead and abdomen. The anterior fontanelle admitted the ball of the middle finger; the commencement of the sutures might be traced from it. The muscles at the back of the neck were rather stiff; any attempt to move the cervical spine was resisted as if it caused pain. When not meddled with, he lay perfectly quiet.

July 20th. He was still drowsy, taking no notice unless roused. When disturbed, he cried fretfully, and the right leg became rigid. The pulse was irregular in rhythm for the first time. The breathing was regular. There had not been any vomiting.

July 28th. The temperature, which had been fluctuating between 100 deg. and 102 deg. for several days, rose to 103.2 deg.; pulse 128; breathing 28. The eyes were examined by Dr. Goodhart; both discs were puffy, with blurred edges.

July 31st. He died comatose, without convulsion. The temperature rose from 103 deg. to 106 deg. before death.

*Post Mortem Examination.*—The body was thin, not emaciated; plenty of subcutaneous fat. Rigor mortis was universal. The right lung was adherent; the adhesions were old and tough. The lower lobes were congested. The bronchial glands were enlarged and cheesy. The heart and abdominal viscera were normal. The anterior fontanelle was open; the parietal bones were not solidly united, but the sagittal suture did not gape. The skull was rather large. The cranial vault was much thinned and translucent in patches. The orbital plates of the frontal bone were not depressed. The convolutions were flattened, and the sulci effaced. The pia mater over the convexity was neither congested nor inflamed. Many ounces of clear yellowish liquid escaped from the ventricles as the brain was being removed. There was basilar meningitis, with considerable exudation about the optic commissure. No tubercular granulations were detected either with the naked eye or by means of the microscope (the vessels in the Sylvian fissures were

specially examined). The surface of the pons Varolii and medulla oblongata were smeared with yellowish lymph. The left half of the pons bulged, as if stretched over a mass in its interior. From its anterior edge, a hard nodulated mass, as big as a large walnut, was seen to project. Its surface was coated with inflammatory exudation, on removing which the left motor oculi nerve was seen tightly stretched over the tumour. The left crus cerebri was expanded by pressure to twice its normal width; moreover, its under surface was soft and pulpy. A small patch on the under surface of the right crus, where it touched the tumour, was likewise softened. On washing away the softened tissue, there was seen to be a very extensive, though superficial, loss of substance in the left, a smaller one in the right, crus. The projecting mass was continuous with that embedded in the left half of the pons, whose tissue did not appear to be softened, though it was much stretched. Two other lumps, exactly like that just described, were found: one, as large as a rifle-bullet, in the left hippocampus minor; one, somewhat larger, in the left cerebellar hemisphere, from whose upper surface it projected to a height of about a quarter of an inch. These lumps were hard, somewhat elastic, yellow, with a small central nucleus of white friable material. They shelled out easily, the brain-tissue in immediate contact with them being softened. Microscopically, they presented the usual characters of "scrofulous lumps" or "solitary tubercles". The ventricles were all of them very much stretched, and the corpora quadrigemina somewhat dislocated by the pressure of the tumour in the pons. The softening usually noticed in cases of tubercular meningitis was entirely absent. The optic papillæ were obviously swollen, and their edges very indistinct.

REMARKS.—The following appears to have been the sequence of the morbid changes in this case. First, a pulmonary affection resulting in adhesive pleurisy and enlargement, with subsequent caseation, of the bronchial glands. Secondly, a gradual development of scrofulous lumps in the brain, one of which, by encroaching on important structures, brought on objective symptoms; while the other two (that in the cerebellum and that in the hippocampus minor, naming them in the order of their size and probable age) did not betray their presence during life. The hydrocephalus must have come on gradually, *pari passu* with the tumour in the pons. Thirdly, an acute basilar meningitis, probably in causal relationship with the tumours. Meningeal tuberculosis is not unfrequently associated with the presence of such bodies in the brain, and the distribution of the tubercles often compels us to view them as products of a local infective process of some sort, setting out from the original growth. In the present case, however, no distinct tubercles were found; and the inflammation, roughly symmetrical, could not be positively referred to the basal tumour as its source. Moreover, there was no sign, either of tuberculosis or of meningitis, about the remaining tumours. The sudden onset of the paralysis, and the slight, though decided, improvement which took place, are worthy of note. Sudden palsy in a child is due, as often as not, to a cause which has been long in operation. Cerebral hemorrhage, the typical lesion in which the onset of symptoms is contemporaneous with that of their immediate cause, is rare in childhood. So, too, apparent remission, whether in degree of palsy or in other grave symptoms, is often obscured in the cerebral disorders of children. The optic neuritis in this case was clearly consequent on the meningitis, not on the tumours or the intraventricular effusion. It is interesting, in reference to the commonly received view of the origin of this form of neuritis—that it is due to increase of intracranial pressure—to note that it was absent throughout in the case of simple intraventricular effusion (11), present in Case III only in its inflammatory stage, and present in Case I, where no exaggerated degree of tension can be supposed to have prevailed within the skull. The great rise of temperature just before death is an usual thing. When a child dies of brain-disease, its temperature is either abnormally high or abnormally low. Why it should be high in one case, low in another, it is impossible to say. The heat-regulating mechanism is always out of gear in such cases; what the result of its derangement will be in any given instance, we are not at present able to foresee.

### QUEEN'S HOSPITAL, BIRMINGHAM.

#### CASE OF POISONING BY OPIUM TREATED PARTLY BY ATROPINE.

(Reported by Mr. SPOFFORTH, House-Physician.)

E. P., AGED 35, was admitted three-quarters of an hour after having taken one ounce of the pharmacopœial tincture of opium, shortly after his supper.

When I first saw the patient, he appeared to be in a sound sleep, from which he could be roused with difficulty, though he quickly relapsed. His breathing was slow, his pulse rapid, weak, and feeble; the pupils were contracted to a pin's point, and insensible to the stimu-

lus of light. The skin was bathed in perspiration. His countenance was slightly dusky. There was no vomiting.

The stomach-pump was used at 12.45 A.M., after which he was kept awake by being walked about between two assistants until 8 A.M., strong coffee being freely given.

At 1.12 A.M., one-hundredth of a grain of atropine was injected subcutaneously.

At 1.26 A.M., the pupils were slightly dilated.

At 2 A.M., one-tenth of a grain of atropine was injected.

At 3 A.M., the patient was more sensible. He had a tendency to go to sleep. He danced a jig round the dressing-room.

At 5 A.M., soda-water and strong beef-tea were given. During his sojourn, he had constant retchings and vomitings. There was arching backwards of the body with rigidity of the muscles of the back.

At 8 A.M., he was ordered to bed. He had passed urine. He was still a little drowsy. After he had been in bed a few hours, he awoke, with slight headache; otherwise he did not complain. He was ordered to have a calomel and jalap powder immediately.

At 2 P.M. he got up, well.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 26TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

ON A CASE OF AMNESIA, WITH POST MORTEM EXAMINATION.

BY WILLIAM HENRY BROADBENT, M.D.

THE communication began by recalling some of the hypothetical conclusions of a previous communication, on the "Mechanism of Speech and Thought", in vol. IV of the *Medico-Chirurgical Transactions*. Dr. Bastian's hypothesis of a special "perceptive centre" in relation with each sense was adopted and extended. It was considered that these "perceptive centres" would be situated in convolutions which received radiating fibres; and Ferrier's researches had since located the centres for vision, hearing, smell, taste, and touch in some of the convolutions into which these fibres had been traced, more particularly fibres from the extraventricular portion of the thalamus. It was further considered probable that the formation of a complete idea of external objects would be represented structurally by the convergence of arcuate commissural fibres from each perceptive centre to some part of the cortex not in direct relation with the crus or basal ganglia. A part of this intellectual process would be the association with the idea of a name. On this hypothesis, it would be possible for a breach to be made in the channel of communication between one of the perceptive centres and the "idea-centre" or "naming centre"; and a case was related in which the effects producible hypothetically by a lesion between the visual perceptive centre and the naming centre had actually been observed. A patient, otherwise quite intelligent, could not name the simplest object at sight, or read a word of his own writing. A *post mortem* examination was made. It was pointed out that a lesion cutting off the "naming centre" from the "auditory perceptive centre", or involving the former centre itself, would produce far more complicated symptoms, since the subject would, *ex hypothesi*, not only fail to understand spoken words, but he would not know what he himself was saying. Cases were briefly given exemplifying this condition, but no examination had been obtained after death. In the case which formed the subject of the communication, which was believed to afford another illustration, the brain was examined after death. An omnibus-driver, of intemperate habits, had a fit, of which no accurate account could be obtained, about October 1st, 1877. He had from that time been in the condition in which he was found on admission into St. Mary's Hospital on the 16th. He walked into the hospital, and no paralysis could be detected except very slight paresis of the right side of the face. Sensibility, however, was defective over the entire right half of the body, limbs, and face. The striking feature of the case was that the speech consisted almost exclusively of an inarticulate jargon, in which, however, from time to time, a distinct word or phrase would be heard, such as "if you please", "thank you". It was difficult to make out how far he understood what was said to him, as his replies, though mere jabber, were often appropriate so far as length was concerned, natural in tone and accent, and accompanied by natural gestures and facial expression. He would also address long speeches to those around him, evidently making some urgent request, and he frequently ended by crying. It was obvious that he thought he was giving expression to ideas present in his own mind, but he did not recognise the fact that his language was inarticulate. It was by telling him to do something that his want of compre-

bension of spoken words was made apparent. His invariable response to the command to give his hand was to put out the tongue, and in one or two doubtful instances only was his action appropriate, and then he was probably directed by signs. He did not understand writing. The patient died suddenly on November 6th; and, on *post mortem* examination, softening was found involving a considerable part of the posterior half of the convex surface of the left hemisphere. The greatest depth (three-fourths of an inch) and breadth of the morbid change were seen in a transverse vertical section made at the end of the fissure of Sylvius. Here, the softening reached from near the superior longitudinal margin to within an inch of the inferior and internal edge of the hemisphere. The convolutions affected were proceeding from before backwards, the supramarginal lobule and corresponding part of the inframarginal or first temporo-sphenoidal gyrus; more deeply and in a more advanced degree the postero-parietal lobule, the angular gyrus, and the first and second temporo-sphenoidal convolutions in the same plane; less extensively the middle connected gyrus and the part of the occipital lobe adjacent. The softening involved the temporo-sphenoidal lobe more completely than the parietal lobe. The arteries of the brain were fairly healthy. The membranes over the vertex were opaque, and raised by fluid from the convolutions. No other morbid change was observed. It was considered that the loss of comprehension of words, whether spoken by others or by himself, and the confusion of mind consequent upon his inability to understand or to make himself understood, would account for the condition of the patient; and the interpretation was that this was due to destruction of the channel from the auditory perceptive centre to the higher centre, in which the name is associated with the idea which it symbolises, or to destruction of this name-centre itself. Whether the interpretation offered was exact or not, the case was interesting as an example of the association of a certain loss of intellectual faculties with a lesion of definite extent and seat. It was worthy of attention that the left hemisphere was the one affected; and it would appear from this and similar cases that the exclusive employment of this hemisphere as the way out for language, involved its use as the way in. A comparison of the effects of identical parts of the two hemispheres would be fruitful of results.

In reply to a question from the PRESIDENT, Dr. BROADBENT said that the patient, when desired to write, took the pen in his hand, but held it in an aimless manner.—Dr. R. BARNES asked, with reference to the theory that the speech-centre was developed in connection with right-handedness, what was the condition in ambidextrous persons.—Dr. BROADBENT said that he could not answer the question.

A CASE OF ANKYLOSIS OF BOTH KNEE-JOINTS, WITH SHORTENING TO THE EXTENT OF TWO INCHES OF THE FEMORA, FROM OBLIQUE AND COMMUNICATED FRACTURES.

BY B. E. BRODIE, F.R.C.S.

The communication described a case in which there was fracture of both thigh-bones, together with injury to both knee-joints. Shortening, to the extent of two inches, took place in each thigh-bone, and ankylosis followed the injuries to the knee-joints. The mode of restoring motion was related, and it was stated that motion was ultimately as perfect as before the accident; and it was further stated that, notwithstanding the shortening of the femora, the patient was not less active, whether on foot or on horseback, than before his accident.

A brief discussion followed, in which Mr. MORRANT BAKER, Mr. HULKE, and the author of the paper took part.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 22ND, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Apparatus for the Treatment of Transverse Fracture of the Patella.*—The PRESIDENT brought before the Society a patient fitted with this apparatus, which he had employed for some time past at St. Bartholomew's Hospital. It consisted essentially of a sheet of plaster fitting to the thigh and extending to the upper margin of the patella, with loops on each side of that bone, and of a canvas slipper, between which, acting from the sole of the foot, and the loops in the plaster, such extension was made by means of pulleys as sufficed to draw the upper fragment down to the lower portion of the broken bone. It was easy to regulate the tension; and, when it was thought well for the patient to get up, the apparatus was left on, as it acted just as well when the man was walking about as it did whilst he was recumbent in bed. Practically, the appliance had been found to insure very good results.

*Laryngo-Tracheotomy for Large Multiple Papillomatous Growth in the Larynx: Removal of the Vocal Cords: Preservation of Voice: Co-existence of Thoracic Aneurism.*—Dr. BURNEY YEO introduced the

subject of this communication, who was a labouring man aged 49, and who first came under his observation as an out-patient at the Brompton Hospital on the 13th of last October, complaining of severe and almost constant pain at the upper part of the left side of his chest. He was very hoarse, and had been so for eight or nine years. He suffered much from dyspnoea, and could not lie down in bed. Examination of the chest discovered a distinct pulsation at the sternal end of the second left intercostal space, with a corresponding area of dulness and strongly accentuated second cardiac sound. There was a prolonged, noisy, harsh, and sometimes whistling inspiration heard all over the chest, without any moist râles. Laryngoscopic examination disclosed the existence in the larynx of a large vascular warty growth, apparently pedunculated, and attached to the anterior commissure above the vocal cords. It almost completely filled the upper part of the laryngeal cavity, concealing the glottis and the vocal cords entirely, except during breathing, when a triangular interval could be seen between the growth and the left vocal cord, through which air passed into the air-passages. On the 16th, he was admitted into King's College Hospital, when, amongst other points in his history, he mentioned that, in June last, while helping to pick up an iron rail, he heard something crack, and was suddenly seized with severe pain in the superior cardiac region, from which he had ever since suffered. He was kept at rest in bed for a month, without any amelioration in his condition; indeed, the pain in the chest and the difficulty of breathing were so distressing, that the patient begged for some operative interference. After consultation with Mr. Lister, the operation to be immediately described was performed on November 23rd.

Mr. LISTER described the operation which he had performed. Cricotomy having shown that both vocal cords were implicated in the disease, he at once divided the thyroid cartilage, after introducing into the trachea one end of a bent leaden tube packed with thin sheet India-rubber, so as to plug the canal completely and prevent danger from blood entering the air-passages, chloroform being given at the other end of the tube. Both vocal cords were removed entire, together with neighbouring portions of mucous membrane, including the false vocal cords. The sides of the thyroid cartilage were drilled and tied together with silver wire, and the edges of the skin over the thyroid cartilage were kept in a state of relaxation by means of the button-stitch. The great peculiarity of the case consisted in the fact that the patient retained the power not only of coughing, but of speech of considerable power. In order to explain this, Mr. Lister referred to observations which he had made in 1861 upon the movements of the larynx, and published shortly in the article "Anæsthetics" in Holmes's *System of Surgery*. He had then ascertained by laryngoscopic examination in his own person, after an experiment on one of the lower animals, that the pulpy folds of mucous membrane which surmount the summits of the arytenoid cartilages can be carried forward to the base of the epiglottis by an antero-posterior movement of the cartilages not generally known to occur, so as to act as a secure valve to the opening of the respiratory passage. It is the vibrations of these posterior parts of the aryteno-epiglottidean folds which constitute the mechanism of laryngeal stertor; and it is by their means that the exit of air is prevented during the accumulating pressure in an expiratory act which ends in coughing. Mr. Lister believed that it was still not generally known that the strain of the act of coughing is not borne by the delicate apparatus of the *rima glottidis*, but by these folds of mucous membrane which cannot suffer from such treatment. Knowing this fact, he had anticipated that the patient would be able to cough like other people; but he had not expected him to retain the power of speaking above a whisper. Yet, he might have been prepared for the possibility of such an occurrence, seeing that laryngeal stertor can be produced at will, and by a mechanism which is independent of the vocal cords, and was left intact by the operation. Mr. Lister then himself uttered a sentence in a voice produced by the vibrations of the aryteno-epiglottidean folds; and he stated that, since his attention had been directed to the subject, he had noticed that this kind of voice is occasionally resorted to in ordinary parlance under the influence of mental emotion. When the patient was introduced, the linear cicatrix over the box of the larynx having been exhibited, he showed that he could cough naturally, and also spoke some sentences in a deep gruff monotone, plainly audible to all present.

Dr. BURNEY YEO added, in completion of the history of the case, that inspection with the laryngoscope now showed an entire absence of the normal intralaryngeal structures. In attempts at speech, the aryteno-epiglottic folds were drawn towards the median line, and served as vibrating media. The man had been readmitted into the hospital a few weeks ago on account of the same neuralgic pains caused by his aortic aneurism, the physical signs of which had become more evident. He had been treated by rest in bed,

hypodermic injections of morphia to procure rest at night, and iodide of potassium in doses of thirty grains three times a-day. He had much improved under this treatment; he was now able to lie down comfortably in bed on either side. He had no dyspnoea and no cough. The expansile impulse and the area of dulness were less. Dr. Yeo thought the case of great interest not only on account of the curious physiological fact it had revealed with respect to the production of voice, but also from the remarkable coincidence of the existence of these large intralaryngeal growths together with thoracic aneurism. In pre-laryngoscopic times, it would have been difficult to avoid the error of regarding the hoarseness and the obstruction to respiration observed in this case as consequences of aneurismal pressure. It was another instance, and a very remarkable one, of the clinical value of the laryngoscope.

The PRESIDENT considered the case now brought under the notice of the Society one inviting consideration and discussion, not merely from its clinical interest, but also from the physiological question which it raised. It seemed to offer another factor in that series of observations which, beginning with the facts noticed after removal of the tongue, had drawn attention to the manner in which the power of speech was preserved after great interference with the organs usually regarded as being concerned in its production. It had been taught that removal of the entire tongue rendered a man mute, but we now knew that the organ might be taken away and the power of speech retained; and now Dr. Foulis's case and the one at present before the Society pointed to further interference with the organ producing the voice, allowing the retention of modified speech or the production of speech by artificial aids. The question of the compensatory action of the aryteno-epiglottidean folds after the removal of the vocal cords was one which would, no doubt, attract further observation, for it was a point of practical importance.—Mr. MAUNDER said the case under consideration was of interest from physiological, clinical, and operative points of view. Doubtless, it was shown thus early after operation, lest the man should die of his aneurism; but he trusted Dr. Yeo would cure this, and would give the Society an opportunity of knowing whether or not the growths recurred. This was important in connection with a case, shown elsewhere by Dr. Foulis, where the papillomata had returned twice, and then excision of the larynx was resorted to. It is very desirable to know ultimate results, in order to settle the question of choice of operation.—Mr. HOLMES said that the case would have been more complete had any anatomical proof been given of the entire removal of the vocal cords, especially as, in the ordinary operation of thyrotomy for the removal of warty tumours from the larynx, no necessity was generally found for doing more than removing at most their surface. He also said that, in reference to the supposed power of the aryteno-epiglottidean folds to produce vocal sounds by their vibration, it would be interesting to know whether any laryngoscopist had ever observed such vibrations during the production of the hoarse voice which Mr. Lister imitated, or during any other kind of phonation. Mr. Lister's own experiments, of course, referred to a peculiar and forced position of the tongue and to the production of a mere inarticulate sound.—Mr. LENOX BROWNE said that, having had an opportunity of examining the patient, he could bear testimony to the fact that every portion of the vocal cords, true and false, had been removed. It appeared to him that in the act of phonation in this case there was general lateral compression of the larynx; there was certainly also a disposition for the epiglottis to hang lower than before the operation, so as to come into greater proximity to the arytenoid cartilages. The case was exceedingly interesting and important, because the operation had been performed not only on account of impairment of voice, but for relief of a vital symptom; and although there were dangers in the operation, they were, in point of fact, not so many nor so great as were frequently witnessed in attempts to remove growths *per vias naturales*. In this latter operation, he had personally witnessed the following consequences: spasm of the larynx, resulting from the introduction of instruments, in two instances, requiring immediate tracheotomy; removal of normal tissue, leading to ulceration; injury to laryngeal cartilages, especially the arytenoid, resulting in paralysis, caries, and death of the patient. There was further a much greater tendency to recurrence than was generally supposed, and the recovery of the voice was by no means so complete as was generally thought to be the case by those who had not an opportunity of personally witnessing the results. Mr. Browne considered that removal of the tracheal tube so very shortly after the operation, in the present instance, had contributed greatly to the patient's rapid recovery, while the very complete enucleation of the contents of the larynx would lead one to predict with almost certainty that there would be no recurrence; and he believed that were these two points, justly insisted on as important by Mr. Lister, rigidly adhered to in similar cases, there would not be necessity for the

much more dangerous operation of extirpation of the larynx.—Dr. F. SEMON was anxious to know why, before performing thyrotomy, no attempt was made to remove the growth by endolaryngeal operation, it being situated above the vocal cords. It had been said that it was too large and too hard to be removed by such an operation; but this reason did not at all seem sufficient to his mind to justify thyrotomy, it being clear that a growth was the easier to remove *per vias naturales* the larger it was. On the other hand, Professor Sörck of Vienna had proved, by removing enchondromata in several instances with his guillotine, that even the highest degree of hardness did not offer a serious obstacle for the endolaryngeal removal of laryngeal growths. If tracheotomy only had been performed, with subsequent endolaryngeal removal of the papilloma, he would not have raised any objection; but he did strongly object to thyrotomy, in consequence of his own experience, as well as from the perusal of a quite lately published book of Professor Paul Bruns of Tübingen—*Laryngotomy for the Removal of Intralaryngeal Growths*—towards which he wished to draw the attention of the Society. In this work, the author, who is Professor of Surgery in the University of Tübingen, compared the value of the intra- and extra-laryngeal methods very impartially, based upon the statistics of all the cases on record until the end of 1877. He came, after careful consideration, to the result that the intralaryngeal method was in most cases by far to be preferred. His results were very striking, and showed clearly the great danger of thyrotomy for the restoration of the voice, as well as for the possibility of recurrence. Out of thirty-nine selected cases of thyrotomy for the removal of growths (the result of all cases on record being still much more unfavourable), only eighteen ended in complete or nearly complete restoration of the voice; while in twenty-one—*i. e.*, in more than 50 per cent.—the voice was finally either completely lost or very much altered. At the same time, there was exactly the same unfavourable percentage of recurrence of the disease. In thirty-nine cases in which papillomata were removed by thyrotomy, the growth returned in twenty-one cases. This was not at all astonishing, if one remembered that thyrotomy was a very tedious operation, which took from one to two hours; that almost during the whole time the narrow space in which one had to operate was filled with blood; and that, if there were multiple papillomata in the larynx, a single small one might easily escape the attention of the surgeon; or that the mucous membrane from which they grew might not be deeply enough destroyed. In such cases, experience showed that, after the operation, the papillomata grew very rapidly again. Hence the comparatively numerous reports of repeated thyrotomies on the same patients. On the other hand, the endolaryngeal method could already now show more than one thousand successful removals of growths. Even if the operation did not succeed, there was at least not a new factor added by the operation itself, so dangerous for the voice as thyrotomy had proved to be. Further, Bruns' statistical tables showed that, in ninety cases of removal of papillomata (most of which were multiple) by endolaryngeal operations, there were only thirty recurrences; *i. e.*, 66 $\frac{2}{3}$  per cent. successes, against the 53 per cent. failures of thyrotomy. These numbers spoke for themselves. With regard to Mr. Lister's physiological remarks, Dr. Semon did not doubt in the least their accuracy; but, as he had made his observations in two instances only, so small a number did not seem sufficient to base upon it any general conclusions. It was a well-known fact amongst laryngoscopists, that some parts of the larynx could take vicariously the functions of others; *e. g.*, the epiglottis being destroyed by syphilis or any other disease, the ary-epiglottic folds or the false vocal cords could protect the larynx against the entrance of food and fluids; or, the vocal cords being ulcerated and almost destroyed, the false vocal cords could act for them during phonation. Also, it was sometimes to be observed that the upper part of the larynx in some patients was so irritable, and at the same time so flexible, that it could be closed completely above the false vocal cords (in which fact the instances related by Professor Lister found their physiological explanations). Dr. Semon thought these cases were only exceptions, and not reliable at all to found upon them any principle of acting; and he did not think the single result obtained by Mr. Lister in this case, however excellent, would induce him to perform thyrotomy as long as the much less dangerous endolaryngeal method was at his disposal.—Mr. ERNEST HART remarked that several of the speakers had referred to the aneurism with the intimation that it would be likely to prove fatal; but he was sure they would be pleased to say, *Abist amen*. By way of practical postscript to that effect, he would like to say that, in all probability, aneurisms ought now to be considered as curable rather than incurable diseases, and that whether they were medical or surgical aneurisms. He had lately seen in the museum of Dr. Steevens's Hospital in Dublin a preparation of a cured consolidated aneurism of the first portion of the arch of the aorta, of which the clinical history very

much resembled that of the present case so far as the aneurism was concerned. The patient had subsequently committed suicide for reasons connected with his pecuniary affairs. The patient had been treated by Mr. Tufnell on his well known method, and there seemed to be no reason why this patient should not be treated by the same method of restricted diet and rest with the prospect of an equally successful result.—Mr. LISTER, in replying, said that, with reference to Mr. Holmes's remarks, he must beg Mr. Holmes to take his word for the fact that both vocal cords were removed in their entire length and thickness, including the anterior processes of the arytenoid cartilages into which they are inserted; or, if that were not sufficient, he would appeal to Dr. Yeo, who was present at the operation. Mr. Wood also kindly assisted at the operation, and, if he had been at the meeting, he would have confirmed the accuracy of the statement.—Dr. BURNEY YEO, in replying, said there could be no doubt whatever that the whole of the strictly intralaryngeal structures had been removed by the operation. He had had opportunities of demonstrating this fact laryngoscopically to several gentlemen present. The patient had not made so good an appearance that evening as he had done on other occasions, being probably a little disturbed by coming before so large an assembly; but his voice had been tested in every way, and he was able to pronounce all the vowel sounds and to read distinctly anything that was put before him. With regard to his aneurism, it was possible that a cure might be effected; but, of course, that was always a matter of great doubt; at any rate, he was in a much better condition than formerly. Moreover, he was certainly *alive*, as the members present could testify, although he had heard it authoritatively stated that this patient was dead.—Mr. HOLMES, in answer to an observation from Mr. Lister, implying that he had questioned the justifiability of the operation, begged to explain that he had said nothing that would bear such an explanation. All that he had said was that, in a case so novel, and on which new physiological views were based, it would have been better if distinct anatomical proof had been adduced of the total removal of the vocal cords. Again, in answer to Dr. Yeo, who represented him as not believing that the cords had been removed, Mr. Holmes begged that he might not be misrepresented. All he had said was that distinct anatomical details would have made the case more complete.

*Sequel of a Case of Subperiosteal Excision of the Os Calcis.*—Mr. HOLMES brought forward the sequel to this case, which is to be found recorded in the Society's *Transactions*, vol. viii, p. 77. The operation was performed on January 31st, 1874. The boy recovered, but with much inflammation, and loss of motion of the ankle. He died of phthisis last autumn, having had a fairly useful foot, though by no means so good an one as was usually obtained by the ordinary excision. The specimen showed that the posterior tarsal bones, astragalus, cuboid, and scaphoid, were ankylosed together by bony ankylosis, and the astragalus to the bones of the leg. There was a very small shell of bone reproduced to represent the os calcis; and to this the tendo Achillis and the muscles of the calcaneum were attached. But this was of no practical utility, nor was the heel more filled out than it usually is after the common operation. On the whole, the anatomical examination of the foot proved beyond doubt that, in this case at any rate, the subperiosteal had given a less satisfactory result than is usually obtained by less tedious dissection.

Mr. MAC CORMAC asked Mr. Holmes whether the suppuration in his case had been long-continued after the operation: for the retention of the bone-making properties of the periosteum depended very largely on the absence of any protracted suppuration, by which these properties were, in fact, destroyed.—Mr. FURNEAUX JORDAN said that he had lately performed the modification of Syme's operation as proposed by Mr. Bell, viz., dissecting off the periosteum from the os calcis and applying it to the sawn end of the tibia. The result was the formation of a convex plate of new bone, which gave a rounded form to the stump and made it more like a new heel. He asked whether this new bone would be liable to take on caries, just as frequently happened in partial operations on the foot for disease to the tarsal bones which had been left behind.—Mr. MAUNDER said he thought the reproduction of bone in subperiosteal excisions depended upon the amount of force requisite for its removal. Rough usage with the raspatory, often unavoidable, gave rise to acute inflammation and destruction of the membrane, whereas in some instances the periosteum peeled off so readily that it would be difficult to take it away with the condemned bone. He deemed it desirable, in some instances, to save even the shell of the os calcis, lest the natural elasticity of the foot should be damaged by a section of plantar ligaments, and so the astragalus, being unduly compressed, might also become carious.—Mr. HOLMES, in answer to Mr. Mac Cormac, who had inquired about the length of the period of suppuration, stated that the suppuration

was extensive and protracted, and very probably testified to a severe inflammation in which the periosteum was more or less destroyed. This was one of the risks attending the protracted violence necessary to separate it from the bone.

*Excision of the Lower End of the Rectum.*—Mr. HOLMES related this case. The operation had been performed upon a woman for disease, apparently of an adenomatous character. The lower end of the bowel was occupied by a series of tumours which occupied and almost filled it, producing almost total stoppage—a case which would certainly justify colotomy in the opinion of most surgeons. About two inches of the whole circumference of the bowel, together with a great quantity of the surrounding tissues, were removed; and, as one of the tumours trenched on the vagina, an opening was necessarily made into the latter cavity. The case did very well; the patient regained her health rapidly, which had been much impaired, but did not recover any sphincter power. The object of the communication was to show that the operation was superior to colotomy in cases of limited disease of the lower end of the bowel, and to urge the surgical members to give it a trial in appropriate cases. Its main advantages were: 1. That it removed the disease which was left to make progress when colotomy was performed; 2. That in some cases (probably those in which the parts around the anus were not very freely removed) some amount of sphincter power was retained, and the patient had sometimes entire control over the motions; and 3. That the artificial anus, even when no more control existed than after colotomy, was in a more convenient position.

Mr. HULKE mentioned that his former colleague, the late Mr. Charles Moore, had, in the Middlesex Hospital, excised the lower end of the rectum in three cases. There was very copious bleeding, checked with difficulty, and the patients soon succumbed. These cases were not well suited for this operation, inasmuch as the tissues outside the gut were much infiltrated. Where this had not happened and the disease was limited, as in Mr. Holmes's case, he quite concurred with him in the advantage of excision. From his own experience of colotomy, done often at a relatively early phase of the cancer, before obstruction, and for the relief of the suffering caused by the contact of the feces with ulcerated surface, Mr. Hulke was disposed to place the duration of life after colotomy as much longer than the time mentioned by Mr. Holmes. With regard to the relative facility of excision and colotomy to which reference had been made, Mr. Hulke thought that, whilst colotomy where the gut was distended must be looked upon as an easy matter, this was not so when the gut was empty, where often much difficulty was experienced.—Mr. THOMAS SMITH remarked that, whatever might be the respective merits of the two operations, colotomy and removal of the rectum, they could not fairly be compared the one with the other. In the event of a patient needing colotomy for cancer of the rectum, the disease would be so advanced that no question of removal of the rectum could be entertained; whereas, if the disease were in an early stage and so limited as to be within reach of removal by operation, the necessity for colotomy would not have yet arisen.—Mr. HENRY MORRIS did not consider that the operations of colotomy and excision of the lower part of the rectum were not comparable, as they were respectively required in different conditions. With respect to the comparative difficulty of the operations, it was true that colotomy was exceedingly easy when performed under favourable circumstances and when the colon was distended, but so was the excision of the rectum. Mr. Morris had never had an opportunity of performing the latter operation himself on the living, but had practised it on the dead subject, and had come to the conclusion that the only trouble likely to arise during the operation was hæmorrhage. He inquired of Mr. Holmes whether he found that hæmorrhage occurred more freely during the detachment of the bowel from the ischio-rectal fossa, or from the division of the gut itself by a transverse section. Referring to the risk of injuring the peritoneum during the operation, he quoted certain experiments by Dr. J. E. Roberts of Philadelphia to show that, when the anus and bowel were undisturbed, the average distance of the peritoneum from the anus was from one inch and a quarter to two inches; but that, when the bowel and anus were detached from their surroundings and straightened out, the average distance was from three inches and a half to four inches and a quarter. This showed the great importance, in order to avoid wounding the peritoneum, of detaching the tube freely from its ischio-rectal surroundings, and of making traction upon the anus before severing the diseased portion of the rectum from the rest of the bowel. He next inquired if any union took place between the lower end off the gut and the edges of the wound, or if the parts healed entirely by granulations; and also if, after healing, there was any tendency to stricture of the artificial anus. Finally, he asked for details respecting the exact mode of operating in this particular case. Three methods had been adopted by different operators; viz., the oval in-

cision, whereby the anus was encircled and the bowel with the anus was loosened from its attachments; 2. Lateral flaps made by one straight incision from the central point of the perineum to the coccyx; 3. A posterior flap made by a transverse incision in front of the anus. In both the latter operations, the external sphincter was saved with the skin of the anus; but these methods were, of course, only feasible when the anus was not involved to any extent in the disease; was this the case in Mr. Holmes's patient?—Mr. F. JORDAN said that, a few years ago, he had excised the rectum of a middle-aged woman for epithelial cancer. He removed it by a circular incision around the rectum, and cleared out the ischio-rectal fossa. About two inches of bowel were taken away, and the hæmorrhage, which was less than he expected, was controlled by sponges and pressure. The rectum acted as before the operation, although no sphincter had been left. No sutures were employed, on account of the high position of the bowel. The woman made an excellent recovery, and he believed she lived eighteen or twenty months afterwards. In a case of cancer of the vulva, he had removed the whole vulva, the vaginal orifice, and two-thirds of the rectum. That was two years ago, and the patient remained well.—Mr. HOLMES agreed with Mr. T. Smith that, if the operation became a recognised one, it might hereafter become possible to assign a different province to it and to colotomy. But at present the operation of excision of the rectum was hardly practised at all in the London hospitals; at least he had never seen it done or heard of it; for the operations referred to by Mr. Hulke, as performed by the late Mr. Moore, had not, as far as he knew, been published (Mr. Hulke assented). With regard to the number of persons surviving a year after colotomy, he was quoting from memory out of Mr. Cripps's essay. He had no information on the point himself, but could easily believe it. In answer to Mr. H. Morris, he said that the bleeding in dividing the wall of the bowel itself was quite insignificant. The only free hæmorrhage was in the ischio-rectal fossa. In answer to Mr. Morris, he said that he was acquainted with the observations of the American surgeon referred to. They were, perhaps, as trustworthy as any other observations made after the admission of the air into the peritoneal cavity; but it was quite evident that the latter fact deteriorated seriously from their practical value.

## MEDICAL SOCIETY OF LONDON.

MONDAY, FEBRUARY 18TH, 1878.

*On the Treatment of Broken Nose by Forcible Straightening, and the Subsequent Use of Retentive Apparatus.*—Mr. WILLIAM ADAMS exhibited to the Society some improved instruments for the treatment of broken nose, a subject which he had first brought before the Society in March 1875 (BRITISH MEDICAL JOURNAL, October 2nd, 1875). He divided the cases of broken nose into two classes. 1. Those in which the cartilaginous septum was depressed and bent laterally, so as to plug one nostril, obstruct the breathing, alter the voice, and produce ozæna by the decomposition of retained mucous secretion; 2. Those in which the nasal bones were fractured in addition to the lateral bending and partial displacement of the cartilaginous septum. The operation which Mr. Adams had proposed was to straighten the bent cartilaginous septum by large flat-bladed forceps, and, when possible, to raise the lower margin of the fractured nasal bones; afterwards retaining the septum in a straight line with the vomer and perpendicular plate of the ethmoid bone by an ivory clamp, and also retaining the nose in an improved position by a nose-truss worn externally. The large flat-bladed forceps originally used by Mr. Adams in 1861, when he first successfully performed the operation, had not been improved upon; but the retentive apparatus for the septum, and the nose-truss applied externally, had been materially modified and improved, and various modifications were exhibited to the Society. The steel screw-compressor and the large ivory plugs were now replaced by the ivory clamp with rack-and-pinion movement, first made by Mr. Ernst; and the retentive nose-truss, consisting of a broad metal forehead-band, with two double-action rack-and-pinion movement levers, with adjusting plates, had been greatly improved by Mr. Huxley. The necessity of retentive apparatus in cases of broken nose had been questioned by some surgeons from the absence of the causes of displacement by muscular action met with in the extremities and other parts of the body; but, if it could be dispensed with in some cases of recent injury, Mr. Adams considered that it never could be dispensed with in cases of some months, and frequently of several years after the injury, and these were the cases which had generally fallen under Mr. Adams's observation. He especially drew attention to three cases now under his care, all occurring in young ladies between thirteen and sixteen years of age, who had met with accidents eight or ten years previously by falling downstairs, or similar

injuries. Increasing deformity of the nose was observed at this period of development; and, upon examination, one nostril was found to be completely plugged by lateral bending of the cartilaginous septum; the breathing and the voice were both interfered with, and ozæna generally existed. In these cases, the nose was completely and permanently straightened by the plan of forcibly straightening the septum, and afterwards continuing the use of the retentive apparatus, the ivory clamp being used continuously for three or four days and nights, and afterwards at night only; whilst the nose-truss was worn during the day for several months.

## SOUTH-EASTERN BRANCH: EAST AND WEST SUSSEX CONJOINT DISTRICT MEETING.

NOVEMBER 30TH, 1877.

F. A. HUMPHRY, Esq., in the Chair.

*Lardaceous Disease.*—Dr. WITHERS MOORE made some remarks on lardaceous disease, suggested by a case which occurred in his practice at the Sussex County Hospital. After a brief sketch of our present knowledge as to the nature, cause, and course of the disease, in which Kyber's statement as to the liability of the aorta and its primary branches to be infiltrated with the deposit was duly noted, Dr. Moore read the case, which was that of a boy aged 9, who had been ailing more or less for four years. The great size of the liver and spleen, together with the condition of the urine, both analytically and microscopically, left no doubt as to the nature of the case; but it was complicated with great contraction of the left chest, and in the same region dulness on pressure, with almost complete absence of breath and voice sounds save at the apex, and lateral curvature of the spine to the right. The pathology of the case was not easy to determine; for, while there were certain facts in its history which favoured the presumption of inherited syphilis being the forerunner of the disease, the massive white teeth, typically clubbed fingers, and general tubercular aspect, seemed to negative it. In the absence of any present or past purulent discharge, chronic fibroid phthisis suggested a possible parent; but the very great contraction of the left chest, together with the results of its physical examination, and, in addition, the spinal curvature, determined Dr. Moore to treat the case as one of lardaceous disease following upon an unresolved empyema; and this diagnosis was fully borne out by the *post mortem* examination, the left pleura containing much pus, and the corresponding lung being reduced almost to a fibroid mass.—A short discussion followed, in which the CHAIRMAN, Dr. MOON, Dr. HOLLIS, and Mr. BRANWELL took part.

*Lead-Poisoning.*—Dr. FUSSELL read notes of a severe case of lead-poisoning. It occurred in a stalwart gamekeeper, aged 53, living in a remote part of the county, who had been confined to his house for some months, and to his bed for many weeks, with urgent symptoms of disease, supposed to be caused by cancer of the bowel. He was admitted into the Sussex County Hospital in October 1876. He was a very temperate man, and before this illness had never suffered from any serious complaint. His aspect was sallow and dejected, lowness of spirits being very marked. The tongue was clean, pulse regular, and temperature normal. He felt excessively weak, had lost flesh rapidly, and complained of pains in all his limbs. The feet and legs were cedematous. For a long period, he had been suffering from what he described as a constant uneasiness in his bowels, which were usually more costive than relaxed; he had never had colic. On several occasions, he had passed small quantities of blood, but had never suffered from piles. One day, when he was shooting with his master, he was seized with sudden and severe pain for a few moments in the abdomen, was forced to evacuate his bowels, and at the same time passed much blood, nearly a teacupful he thought. He could not attribute this seizure to anything he had eaten. A most careful manipulation of the abdomen failed to give any signs of malignant or other disease, and an examination *per rectum* also gave negative evidence. The thoracic organs appeared to be healthy. The motions seemed natural, and the urine contained no albumen or sugar, and was of normal specific gravity. There was no paralysis of any muscle, and no tremors. Thus no disease was at first detected, so that Dr. Fussell would give no opinion upon the case; yet, the man was slowly dying. At a subsequent examination, a faint blue line was found on the gums, but so faint that, had it not been for the marked symptoms, no notice might have been taken of it. A bottle of his drinking-water was then procured, which gave traces of lead, and lead was found in his urine. On visiting his cottage, the wife was found to have been for some time subject to what she termed bilious indigestion, constipation, and uneasiness in the bowels, but there were no traces of lead on her gums. The daughters, aged 12 and 14, had not suffered in any way, and their gums were quite

free from deposit. The man was treated with large doses of iodide of potassium, aperients, warm-baths, and friction to the skin. He left the hospital in two months, much relieved; and Dr. Fussell met him about four months ago with his dog and gun, apparently well, but still feeling weak. There was a long leaden pipe into the well. The water sent to the hospital was taken from the well about the middle of November, soon after the man's admission, before the springs had risen to any great extent. A sample of water from the same well was taken in the month of February following, and sent to a London analyst, who could find no lead in it. This might have been owing to the state of the springs, or to the fact that the sample was taken after there had been much purifying. The case was remarkable in many ways. Had the man died at home, it might have been tabulated by the Registrar-General as "cancer of the bowel". It was truly difficult of diagnosis. There really no marked symptom of lead-poisoning, save the faint line on the gums. The wife, who had been suffering from the same symptoms to a slight degree, had no such mark. The man had been drinking the poisoned water for a considerable period, therefore was very slowly affected by it, and did not exhibit any of the more pointed symptoms of lead-poisoning. Dr. Fussell then referred to several cases of lead-poisoning in which the cause was difficult of detection; notably, the cases reported by Dr. Alford of poisoning by the under surface of a millstone being honeycombed with lead; a case of the man poisoned by being the first customer in the morning at a public house; also a case recorded by Sir Thomas Watson, who was called to the Isle of Wight to see a lady who had been attacked with convulsions, became comatose, but ultimately recovered.—Dr. HALL and Mr. WM. WALLIS related cases bearing upon the paper.—Dr. FULLER made remarks touching upon the various modes of contamination of water by lead.

#### ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, DECEMBER 5TH, 1877.

FRANCIS OGSTON, M.D., President, in the Chair.

*Obstruction of the Bowels.*—Dr. URQUHART read a paper on this subject. After noticing the general symptoms, causes, diagnosis, prognosis, and treatment of the disease, the author gave details regarding several cases. One of these cases was caused by feces impacted in the rectum, one by cancer of the lower end of the rectum, one by cancer of the cæcum, one by an impacted gall-stone, which had ulcerated through the gall-bladder into the small intestine, and the cause of one was unknown. All the cases were fatal, except the first and last. In the last case, the obstruction continued for seventeen days, during which time the vomiting continued for the most part stercoraceous, and there was no evacuation from the bowel of any kind. The patient was a healthy young man aged 21. The cause could not be made out with any certainty, as there was no local swelling or other indication of the locality or nature of the obstruction. He recovered under the administration of hypodermic injections of morphia, in doses beginning with one quarter of a grain of the acetate, increasing to one grain three times a day. In the case of obstruction from gall-stone, the patient was a man about sixty-eight years of age, tall and thin. He had had shivering, fever, and intense pain and tenderness in the region of the gall-bladder, about two months before his death. When seen, he was sinking, and, on *post mortem* examination, the gall-stone (which was produced and was about the size of a large walnut) was found impacted in the small intestine, completely closing the gut.

*Tetanus.*—Dr. IRVINE of Tarves read a paper on tetanus, with special reference to two cases he had seen and treated. He began by stating that lock-jaw had been divided into idiopathic and traumatic, the latter being allowed by all to be the most frequent. He had not seen any idiopathic cases. He believed traumatic tetanus was far more frequent in males than in females, and this for the obvious reason that the former were more exposed to injuries likely to be followed by lock-jaw than the latter. Injuries of the extremities and of tendons, and punctured and lacerated wounds, were more apt to be followed by the malady than wounds in other parts and of a different character, such as incised wounds. Very slight injuries, and such as were without breach of surface even, were said to have been followed by lock-jaw; but the author doubted whether tetanus ever occurred without there being some breach of surface. He stated that the balance of opinion among veterinary surgeons, who had more opportunities than medical men of witnessing and treating lock-jaw, inclined to the side that lock-jaw was seldom seen as an idiopathic complaint. Idiopathic tetanus had been attributed to cold; but while cold might fan the flame, as where in the case of the horse the stable was cold and the roof letting in the wind and rain, was it not possible to find a newly healed or scarcely healed

raw behind the shoulders, or a recently closed cicatrix, the mark of a former fall, on one or both of the horse's knees? He had seen a horse fall and slightly graze the knees, which healed shortly; but, in six weeks after the fall, lock-jaw supervened with the usual result. He was inclined, from what he had seen, to doubt the existence of idiopathic tetanus; and to believe that, where an injury had not been discovered, it was owing either to its being so slight as to have escaped observation, or to its not being looked for with sufficient attention. Dr. Irvine then made some remarks regarding the curability of tetanus. He said that, fifty years ago, the disease was considered almost incurable, and that, when he was walking the wards of the Aberdeen Infirmary, the case-books contained but one instance of recovery from lock-jaw. More cases of recovery had of late been recorded, and no doubt, in time to come, still more cures would be effected. One observation he would make on this subject was that the danger was always greater the sooner the untoward symptoms set in. The author then reported two cases. The first was that of a young farmer, who accidentally shot himself in the thigh, inner condyle of the knee, and inside and back of the leg. Seventeen days after the accident, lock-jaw appeared, and was treated without effect by chloroform, the failure being perhaps from not continuing the agent long enough, or using it with sufficient vigour. Tincture of cannabis Indica was then had recourse to, and was administered in doses of a teaspoonful at a time, repeated whenever the effect was wearing off. The patient was kept napping for days and nights together. No other treatment was given, but an occasional dose of calomel, with beef tea and stimulants, when these could be swallowed, and the patient recovered perfectly. The second case was that of a woman about 43, fair, nervous, hysterical, the mother of three children. She had long been subject to attacks of uterine hæmorrhage and leucorrhœa, and was on the whole weak and broken down. She had left home for the sea-side for a few weeks, and on the night of her return trismus came on. On inquiry, it was discovered that when from home excessive hæmorrhage had occurred, which had been checked by plugging the vagina with cotton-wool; and, as some uneasiness in the passage and some difficulty in urinating existed, she was examined, as it was thought there might be an abrasion of the mucous membrane sufficient to account for the attack; but nothing was found in the passage. Repeated hypodermic injections of morphia were used, warm cataplasms and soothing liniment were applied to the fauces, and clysters of strong beef-tea and brandy were administered by the bowels. Chloral-hydrate, in drachm and drachm-and-a-half doses, was injected by the bowels, and seemed to afford relief. After two days, cannabis Indica was tried, but could not be taken in quantity sufficient to be of service. Chloral injections were resumed, and seemed to give relief for about an hour after administration. These injections were continued in quantities of eighty grains at a time. Ten days from the coming on of the trismus, the power of swallowing seemed to be improving, and there appeared a prospect of a successful issue to the case, the chloral being still used twice daily; but, on the afternoon of the fifteenth day, during an attempt to swallow a few drops of water, she exclaimed, "I am choked", fell back on the pillow, and immediately expired, death being no doubt occasioned by spasm of the muscles about the glottis and closure of the rima itself. The author, in his closing remarks, regretted that, when he had found the cannabis could not be given by the mouth in the second case, he had not tried the administration of that medicine, either alone or with chloral-hydrate, by the rectum.

#### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

JANUARY 25TH, 1878.

JAMES THOMPSON, M.B., in the Chair.

*Diffused Traumatic Aneurism.*—Mr. MESSITER of Dudley showed a patient who, in consequence of a punctured wound of the femoral artery, had had a diffused traumatic aneurism. Mr. Houghton of Dudley, three weeks after the accident, cut down upon the artery and tied it above and below the wound. The patient made a good recovery. The anterior tibial on the dorsum of the foot was the only artery to be felt below the ligature after the operation.

*Thoracic Aneurism.*—Mr. A. H. EVANS of Sutton-Coldfield showed a specimen of aneurism of the descending part of the arch of the aorta. The sac half filled the left chest. The heart and its valves showed no signs of disease. The aorta was dilated and calcareous. The mouth of the aneurism was two inches wide. The man from whom the specimen was taken was a brickmaker aged 32, of abstemious habits, and had not had rheumatism or syphilis. The symptoms extended over a period of two years. He first complained of pain in the back and right

iliac region. Two months later, cough and pain in the chest came on; and a diastolic murmur was heard over the sternum. No dulness or pulsation could be detected over the seat of the murmur, nor was there any difference in the size of the pupils or radial pulses; he lost flesh, and bent forward in walking. Three months before his death, as he was getting out of bed to go to work, he felt as though his spine had broken. Examined at that time, there was dulness, with diminished breath-sounds over the back of the left lung, and stridulous breathing over the bronchus of that lung. To avoid pain, he lay on his back from that time until his death, which was caused by hæmoptysis from the rupture of the aneurism into the left bronchus.

**Cystic Calculus.**—Mr. ORWIN of Dudley showed a calculus, having a piece of slate-pencil for its nucleus. It had been extracted from the bladder of a female by lithotripsy.

**Cancer of Lung.**—Dr. EDGINGTON showed a specimen of the lung.

**Sarcoma of the Tibia.**—Mr. LOWE, in the absence of Mr. GOODALL, showed a specimen of sarcoma of the tibia, removed by amputation of the thigh. The patient, who was twenty-five years of age, discovered the tumour in July last. In September, as he was making a severe muscular effort, he felt the bone snap at the seat of the tumour. This fracture never united, but the tumour at once commenced to grow very rapidly, and became pulsatile; it was throughout painless. Examined after removal, the tumour was found to involve the whole of the tibia transversely, producing a globular expansion of the bone. Structurally, it was a round-celled sarcoma.

**Cancer of Liver.**—Mr. LOWE showed a liver, which was infiltrated throughout with cancerous nodules, and weighed eleven pounds. The liver-affection was secondary to cancer of the stomach. The specimen was taken from a woman aged 35.

**Graves's Disease, with Unilateral Exophthalmos.**—Mr. EALES showed a case of Graves's disease, with unilateral exophthalmos of the right side. The patient, a servant aged 22, had suffered from exophthalmos for eight years, associated with enlargement of the thyroid gland, which was most marked on the right side; there was anæmia; the pulse was irregular and intermittent; a systolic hæmic murmur was heard over the base of the heart and over the large vessels of the neck; and there was reduplication of the first sound of the heart. Menstruation was scanty and irregular. The pupils were of the same size. The right side of the face seemed more developed than the left. The retinal vessels in both eyes were full and tortuous, especially the veins. There was no difference in the two eyes in this respect. The right eye protruded about half-an-inch, but there was no displacement to either side or interference with the action of the recti muscles. Hypermetropia was present in both eyes, but to a greater extent in the right than in the left.

## PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, JANUARY 26TH, 1878.

JOLLIFFE TUFNELL, F.R.C.S.I., in the Chair.

**Atheroma of Aorta: Mechanical Hyperæmia of Organs.**—Dr. J. W. MOORE exhibited the thoracic and some of the abdominal viscera of a man aged 73, long the subject of gouty eczema of both legs. Extensive endoarteritis deformans chronica of the aorta and its main branches led to the following sequence of pathological events: dilatation of the ascending aorta, hypertrophy, and subsequent dilatation of the left ventricle of the heart; dilatation of the mitral orifice and of the left auricle; passive hyperæmia of the lungs; remarkable dilatation of the pulmonary artery, right chambers of the heart, and tricuspid opening. The liver was in a condition of red atrophy (nutmeg liver); and the kidneys were the seat of a chronic passive congestion, with interstitial nephritis. There was some anasarca and ascites.

**The Cure of Thoracic Aneurism.**—Dr. HEAD exhibited a cured aneurism of the arteria innominata from the body of a gentleman aged 56, who unapparently committed suicide while labouring under mental depression. The deceased became subject to neuralgia in the right shoulder and up the back of the neck. Last July, a dusky spot and an area of indistinct pulsation underneath the cartilage of the right second rib, with a slight difference in the right radial pulse, and enfeebled respiration in the right lung, led to the diagnosis of aneurism of the innominate artery. Mr. Tufnell, who visited him in consultation, agreed in this diagnosis; and, as the aneurism sprang from the anterior aspect of the vessel, the patient was treated by rest in the horizontal posture and by limited diet from the end of July to the beginning of October. At this latter date, the heart was displaced downwards, and appeared somewhat enlarged. The strong impulse of a solid body was felt to the right of the sternum near the first and second ribs. The impulse was slightly presystolic. In the middle of January, the patient threw him-

self into the river Liffey, and, although rescued, died of the shock in a couple of hours. A solid tumour, adherent to the undersurface of the sternum, was found in the anterior mediastinum. There was no solution of continuity or extravasation of blood. The heart was covered with fat. Its left ventricle was dilated, but the valves were healthy. The aorta presented an extreme example of atheroma. It was dilated into pouches, forming true aneurisms in several places. The arteria innominata formed one large aneurism, which had been perfectly cured by the deposition of successive fine laminae of fibrin in its sac.—Dr. LYONS asked whether the suicidal act had been induced by pain, or depended on any hereditary tendency.—The CHAIRMAN said monetary anxiety led to the suicide. He then detailed his method of treatment of aneurism by rest and diet, for the success of which three conditions were essential, viz.: 1. The aneurism must spring from the front of the vessel; 2. The sac, no matter how formed, must be perfect; 3. There must be a fibrinating power in the blood.

**Past Abdominal Aneurism.**—Dr. HAYDEN exhibited an enormous aneurism of the abdominal aorta in a thin spare man aged 42, of very intemperate habits. The first symptom was shooting pains in the back radiating through the abdomen. Afterwards, a swelling came in the left loin; and lastly, a large tumour appeared in the epigastrium. At first, no murmur was heard, but subsequently a blowing systolic bruit became audible. Change of position did not affect the pulsation. Diet, with rest in bed and twenty-grain doses of iodide of potassium thrice daily brought about an apparent improvement, signalled by the firm feel of a large portion of the tumour. But in a few days death occurred most suddenly. A rent had taken place in the posterior wall of the aneurism, and an enormous extravasation of blood had infiltrated the iliacus and psoas muscles, forming a large false aneurism, in which the blood deposited quantities of firm fibrin. Thus was explained the apparent consolidation in the sac. A second hæmorrhage, into the pleura, was found as the cause of the sudden death. The sac was eleven inches in its antero-posterior diameter. The tumour moved with respiration, owing to its firm and extensive attachment to the diaphragm. There was no hypertrophy of the left ventricle; but the whole aorta was highly atheromatous. The aneurism sprang from the left and anterior aspect of the aorta at the origin of the celiac axis, the superior mesenteric artery arising from its inferior surface. There was partial erosion of the last two dorsal and first lumbar vertebrae on the left side.

## MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.

WEDNESDAY, JANUARY 2ND, 1878.

SAMUEL GORDON, M.D., President, in the Chair.

**Facial Paralysis.**—Dr. WALTER G. SMITH read a paper on the action of induced currents and interrupted voltaic currents in facial paralysis. The remarkable and extremely characteristic clinical features of Bell's paralysis had been so often and so well described that, in a series of seven illustrative cases, the author restricted himself to a brief summary of those points alone which bore on prognosis and treatment. The series of cases detailed went to show that the prognosis in facial paralysis varied within wide limits, both as regarded duration and completeness of recovery, and that, without the aid of electrical investigation, no accurate forecast could be made. Why some cases were transient and others persistent, depended partly on the nature, position, and intensity of the lesion, and partly on the relative extent of degenerative changes in the muscle and nerve. The more the structural changes were confined to the muscle, the more rapid was recovery. Any attempt to localise the exact seat of paralytic lesion rested on a precise knowledge of the anatomical course of the portio dura, and of the physiological functions of the nerves connected with it. When the relative action of direct galvanic currents and of induction currents upon a sufficient number of recent cases of Bell's paralysis was studied, the great majority distributed themselves among two classes. 1. Cases in which muscular irritability was slightly or not at all impaired towards voltaic or induced currents. These cases recovered speedily, and a favourable prognosis might confidently be made, because the absence of electrical disturbance argued the absence of important structural changes in the tissues. 2. Cases—perhaps the more numerous—in which muscular irritability towards faradic currents was usually markedly impaired, perhaps even appeared totally lost, but in which the galvanic irritability was not only preserved, but actually heightened, for a time. In the nerve, the excitability to either faradic or galvanic currents usually disappeared, and it was a curious and instructive experiment to test with suitable electrodes the relative irritability of the portio dura behind the angle of the jaw and of the muscles on the side

of the face. Whenever this curious phenomenon was well marked, it was an almost certain prognostic of a tedious course of many weeks or months. No explanation of this remarkable fact—viz., the muscle failing to respond to the stimulus of a faradic current, while it readily reacted to an interrupted galvanic current—was forthcoming until 1864, when Neumann proved that, if a galvanic current, which, when slowly interrupted, excited muscular contraction, were very rapidly interrupted by some mechanical arrangement, so as to approximate induction-currents in rapidity, it entirely failed to elicit muscular contraction. He stated also that single shocks of an inductorium failed to cause contraction. The conclusion thence arrived at was, that induced and galvanic currents exercise different actions upon paralysed muscles, because the muscles in certain diseased states have lost their excitability for even intense currents of momentary duration, while they have preserved it for currents whose duration is longer. Neumann's explanation, however, left untouched the paradox of paralysed muscles responding to a galvanic stimulus too feeble to affect the homologous healthy muscles. Neither did Erb, in his recent monograph (*Ziemssen's Cyclopf. Pract. Med.*, vol. xi) attempt to explain this. It was not difficult, however, to conceive how pathological alterations in muscular tissue might render the particles of muscles, to speak hypothetically, less mobile than usual to a rapidly intermitting current, i.e., to a series of quickly recurring excitations; or, in other words, the degenerated muscles—their normal properties being qualitatively and quantitatively changed—were exhausted by a rapid succession of stimuli, and accordingly lose their capacity to respond. Possibly, in some cases, the muscle was thrown into a state of feeble tetanus which was mistaken for immobility. In attempting to account for the curious difference in action between a slowly and a rapidly interrupted electric current, stress should be laid not only on the total duration of the current, but also on the interval between the successive shocks. If variations in rapidity of the oscillations of the current be a principal determining factor of the difference in pathological action of induced and voltaic currents, we ought to be able to demonstrate in a series of cases,—1. That rapidly intermitting induction currents are without effect; this is universally admitted: 2. That rapidly intermitting voltaic currents are without effect; this has been repeatedly verified, and careful observation will, the author believed, show that the first shock produces an initial contraction: 3. That slowly intermitting voltaic currents produce muscular contraction; this is confirmed by all observers: 4. That slowly intermitting induction currents may produce muscular contraction. The key to the solution of the problem of increased readiness of response of paralysed muscles towards a slowly interrupted voltaic current appeared to be that offered by Legros and Onimus—namely, that in certain stages of structural and chemical alteration striped muscular tissue comes to resemble in properties the more simply constituted smooth muscular fibre, and, therefore, is more susceptible than healthy striated muscle to the voltaic stimulus, for smooth muscular fibre is more readily excited by voltaic than by induced currents. Finally, Dr. Smith thought there was ground for holding that facial paralysis might arise in a threefold way; 1. From affections implicating the nucleus of the facial nerve, e.g., in acute ascending paralysis, tabes dorsalis, and bulbar paralysis; 2. From lesions of the trunk of the portio dura nerve, through cold, injuries, etc.; 3. From lesion of the peripheral nerve-terminations through the action of cold.—The PRESIDENT alluded to cases of transient facial paralysis confined to the portio dura district and due to deficient circulation. He also spoke of cases of paralysis of peripheral origin which eventuated in central brain-disease.—Dr. H. KENNEDY mentioned a case of facial palsy, in which mercury pushed to salivation had proved successful. He had observed transient paralysis in syncopal heart-disease. He quoted Dr. Graves to show that the application of cold to the feet and legs was capable of producing facial paralysis.—Dr. AQUILLA SMITH referred to the absolute failure of the mercurial treatment in a series of cases which afterwards did well under electricity.—Mr. H. G. CROLY had seen one of the cases reported by Dr. W. G. Smith. It occurred in a child who had overexerted herself. Numerous remedies were tried unsuccessfully. Very early in the case, he felt a small gland near the stylo-mastoid foramen. It was, perhaps, the cause of paralysis by pressing on the nerve; or it might have been itself due to a blister which was used. The patient progressed favourably under the electrical treatment. He detailed two cases of surgical facial palsy following the removal of parotid tumours, and alluded to the hypodermic injection of minute doses of strychnia.—Dr. FINNY asked what interval should elapse before electricity should be used. He also described an interesting case.—Dr. SMITH, in reply, said he had tried strychnia in several cases of facial paralysis, and had convinced himself that in no case was any improvement due to the use of it. He believed that the sooner electrical treatment was begun and carefully carried out, the better would it be for the patient. Prognosis could not be derived from a single ex-

amination, but must be the result of several examinations made within short intervals of each other.

*A Fatal Case of Typhus, with Hyperpyrexia.*—Dr. J. W. MOORE detailed a case of typhus fever in a woman aged 38, who succumbed on the nineteenth day. The fever was of the ataxic or nervous variety, attended with severe headache, delirium, sleeplessness, subsultus, extreme cardiac weakening, and hyperpyrexia in the death-agony. On three occasions, partial attempts at crisis, chiefly by profuse diaphoresis, occurred. On the morning of the nineteenth day, the axillary temperature was 106.4 deg. Fahr. At 6.45 P.M., she was bathed in a cold perspiration, the extremities were cold, her eyes fixed, with coma vigil. There was considerable albuminuria. Bronchial rales were heard universally over the chest. The axillary temperature (taken twice with two reliable thermometers) was 108.6 deg. She was manifestly dying. At 7.30 P.M., the last observation on the temperature was made. It was found to be 109.1 deg. Three hours later, she was dead. Unfortunately, no observation was made after death. This was partly owing to the late hour at which she died. In commenting on the case, the author discussed some of the modern theories of hyperpyrexia, quoting Dr. C. Handfield Jones on the neuro-pathological view of fever, and Dr. Burdon-Sanderson on the Process of Fever.—The PRESIDENT said the case reported by Dr. Moore was especially remarkable on account of the three efforts at crisis which had occurred in the course of it.

## SURGICAL SOCIETY OF IRELAND.

FRIDAY, JANUARY 18TH, 1878.

PHILIP C. SMYLY, M.D., in the Chair.

*The Late Dr. Stokes.*—Mr. HAMILTON moved that a resolution, expressing sympathy with the family of the late Dr. Stokes in their bereavement, be passed by the Society and forwarded to the relatives of the late esteemed gentleman. He spoke in high terms of Dr. Stokes's worth, and said that not only would his loss be felt in this country, but throughout Europe.—Mr. MACNAMARA seconded the resolution. He said that he had known the late Dr. Stokes for many years, having been first his pupil, and afterwards having enjoyed the privilege of being his colleague in the Meath Hospital; and never did he meet with anything but kindness and consideration at his hands.—After some further remarks by Mr. SMYLY and Dr. BENSON, the resolution was put and carried.

*Exostosis of the Lower Jaw.*—Dr. BARTON exhibited a specimen which he had removed from the face of a young woman aged 17. This growth had existed for four years. There was no history of an accident. The case was successful.

*Displacement of the Ulna Backwards, with T-shaped Fracture of the Humerus extending into the Elbow-joint.*—Mr. TYRRELL exhibited a specimen of these injuries, in the case of a girl whose elbow-joint he excised a short time before.

*Ovarian Cyst.*—Dr. ATTHILL exhibited an ovarian cyst which he had lately removed. It was very large, and had existed several years. The woman from whom the tumour was removed had been tapped several times, but with little or no advantage. The case proved fatal.

*Supposed Fracture of Great Trochanter.*—Mr. TYRRELL exhibited a large pencil which he had removed from the thigh of a man, who had been sent to him for a supposed fracture of the great trochanter. The movable nature of the pencil had caused the error of diagnosis.

*Deformities of the Bladder.*—A postponed discussion on Mr. WHEELER's paper, read at the last meeting, took place. The paper was on the subject of deformities of the bladder, operations for their relief, and certain experiments which he had performed to show the absorptive power of the vesical mucus. Liquor potassæ, morphia, iodine, and prussiate of potash had been used by him with good results.—Mr. MACNAMARA considered it most difficult to make experiments on the bladder, as it was hard to get a patient to micturate at the right moment, and also to be able to discontinue doing so when told. He had been singularly fortunate himself in having had a patient under his care in the Meath Hospital, where the man could do what he was told to do. The case is given in Haughton's *Animal Mechanics*. Mr. Macnamara considered the case to have been most important, as he had been enabled to make experiments with much facility.—Dr. MAPOTHER considered the experiments made by Mr. Wheeler to be most valuable.—Mr. RICHARDSON agreed with the opinion of Sir Henry Thompson, that the mucous membrane of the bladder has no absorptive power. He considered that experiments made on healthy bladders and bladders exposed to the air (as Dr. Wheeler's patient was) were very different. Sir H. Thompson had never tried experiments, as Dr. Wheeler had done, on an extroverted bladder; but Mr. Richardson said that Sir H. Thompson believed that the action of drugs would

not be the same on it as on a healthy viscus. Mr. Richardson stated that he had injected twenty grains of extract of belladonna into the bladder without producing the slightest effect.—Dr. O'LEARY said that, in all the cases in which Sir Henry Thompson had experimented, the bladder had been in a state of inflammation, and, therefore, not in a fit state for experiments.—Mr. HAMILTON considered that the exposure of the mucous membrane to the air had altered its condition.—Mr. WHEELER, in reply, stated that the experiments were most difficult to perform on account of their great tediousness. He brought forward, in support of the theory that the mucous membrane of the bladder did absorb, the fact that it was histologically derived from the same source as that of the vagina, and the mucous membrane of the vagina certainly did absorb.

## MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, JANUARY 16TH, 1878.

J. D. GILLESPIE, M.D., Retiring President, and afterwards W. R. SANDERS, M.D., President, in the Chair.

*Tendon-Reflex.*—Dr. GRAINGER STEWART introduced a series of cases as illustrations of the condition described by Professor Westphal of Berlin as "knee-phenomenon" and "foot-phenomenon", and by Professor Erb of Heidelberg as "tendon-reflex". These gentlemen had each independently discovered these phenomena, and they described them in the same number of the *Archiv für Psychiatrie und Nervenkrankheiten* three years ago. The condition may be demonstrated in connection with many muscles, but is most conveniently shown in connection with the quadriceps extensor femoris and ligamentum patellæ. By tapping firmly and suddenly on certain parts of that tendon, when the leg is in a semi-flexed position, reflex contraction of the quadriceps is produced, and the foot is jerked forward. The amount of irritability varies in different individuals, but is never absent in healthy people. In various diseases it becomes altered. Westphal, Erb, and Berger have shown that it is invariably and completely absent in the advanced stages of locomotor ataxia; and, quite recently, Westphal has announced that he has found its disappearance one of the earliest reliable symptoms of that disease. In chorea, the irritation has been seen to lead to extensive and irregular movements; and there are various other modifications in cerebral and spinal diseases. The first patient introduced was a boy, suffering from right-sided hemiplegia, with partial aphasia. In the left leg, the phenomena of ordinary natural reflex movement was exhibited on tapping the tendon. On the right leg, it was shown that the tapping was immediately followed by the usual jerk, but that the contraction inducing this jerk persisted, so that the leg was maintained for some seconds in a state of partial extension. This condition was associated with various other peculiarities in regard to the function of the muscles, which it was not desired at present to bring under the attention of the Society. The second case was that of a man suffering from well-marked locomotor ataxia, with extreme spinal myosis. In him there was absolutely no "tendon-reflex" to be elicited, while reflex action was readily produced by tickling the soles of the feet. The third case was another example of locomotor ataxia, associated with some degree of multiple sclerosis. In this case also the tendon-reflex was shown to be completely lost. The fourth case was that of a young man who exhibited certain of the symptoms of locomotor ataxia, viz., an ataxic, though not characteristic, gait with increase of unsteadiness on closing the eyes. In this patient there was an increase of the tendon-reflex; and Dr. Stewart pointed out that, according to Westphal's recent observations, this would tend to confirm the diagnosis which had been arrived at from a general consideration of the symptoms, that the case afforded an example of an anomalous spinal affection, different from the grey degeneration of the posterior columns. Reflex movement on tickling the soles was natural.

*Amputation at the Hip-joint.*—Mr. BELL showed the patient, whose leg he had amputated at the hip-joint for a large malignant tumour of the thigh. The tumour itself he had shown at a previous meeting. This case was as yet the only one where antiseptics had been successfully carried out in amputation at the hip in an adult. They could now see the line of union of the flaps, and the large part at the inner angle which had healed by first intention.—The PRESIDENT (Dr. GILLESPIE) remarked that he had never seen a patient suffer less from shock. He had watched him from the day of operation, and had always found him more like a patient with a finger amputated than one whose leg had been removed at the hip.

*Reflex Paraplegia.*—Mr. ANNANDALE showed a boy who had suffered from reflex paraplegia. He was admitted six weeks ago with the history that, shortly after beginning to walk, he had weakness in the legs, and a tendency to fall. When lying in bed he could not get up.

There was no disease of the spine or of the brain apparent, and the paraplegia was incomplete, as he could walk and stand to a certain extent, while sensation was unimpaired, and the sphincters unaffected. A few years ago, Mr. Annandale had a conversation with Dr. Sayre of New York, who sent him some pamphlets on this subject. The boy had congenital phimosis, and therefore, on the supposition that it was related to the paraplegia, he circumcised him on December 19th. The result was marked improvement, as he could now stand pretty steadily, kick out when he was lifted from the ground, and walk better. It was evident that the muscles were not right yet, and he was accordingly getting the galvanic current applied.

*Injuries of the Arm.*—Mr. ANNANDALE showed a lad who had suffered from a rare injury. While bird's nesting, he fell down a precipice, and got a fracture of his right arm, several cuts, and a compound separation of the lower epiphysis of the radius, the shaft being protruded for about one and a half inches, while the epiphysis remained attached to the wrist. In such cases amputation was generally performed. In this case, however, Mr. Annandale cut off the protruding parts of the shaft, after stripping off the periosteum, and also removed the epiphysis, inasmuch as it got its chief nourishment from the shaft. The result was a good one, and the patient had now an useful hand, although about three inches of bone had been removed. A similar case was recorded in Dr. Cruikshank's *Uddi-Mecum*, where amputation was performed.

The PRESIDENT, after thanking the gentlemen who had shown the specimens, delivered his valedictory address.

*The New President.*—Dr. SANDERS, President-elect, then took the chair. It was not customary to deliver any speech, and he would accordingly only tender the members his sincerest thanks for the honour they had conferred on him in electing him the president. The honour was a valuable one, not only because the presidential chair had been filled by most excellent and eminent men, but also because there could be no higher position than to preside over a society whose objects were the diffusion of medical knowledge, the culture of medical science, and the improvement of medical teaching. He trusted that by the communications brought forward the members would keep up the interest of the Society, and make the ensuing session as profitable and instructive as past ones. So far as in him lay, he would endeavour to promote the objects, maintain the dignity, and forward the interests of the Society.

*Scirrhus Tumour of Orbit.*—Dr. ARGYLL ROBERTSON showed a tumour removed from a man beyond the middle period of life. It occupied the floor of the orbit, as far back as the optic foramen. The eye protruded forwards, upwards, and outwards. As it was growing rapidly, and other treatment had failed, he removed it, leaving the eye behind. It was difficult to separate it from the surrounding tissue, and, while doing so, he found a perforation of the inferior orbital plate into the antrum. It appeared, however, to be removed entirely and permanently. On examination, however, it proved to be scirrhus, as it was concave on section, very firm in texture, and with a fine serum, containing numerous typical cancer-cells, polygonal, and many nucleated. As scirrhus of the orbit was rare, he had shown it to the society. He only wished further to mention that it had been kept in chloral.

*Tumours.*—Mr. BELL showed specimens of (1) epithelial cancer of the nipple and scirrhus in the same mamma, and (2) sarcomatous tumour following an injury. As the hour was well advanced, he would say nothing more about the specimens than that the drainage had been conducted according to the method of Mr. McGill, of Leeds. This consisted in having a long drainage-tube, with the part within the dressing perforated with holes. The part outside was non-perforated, and dipped into a jar containing carbolic lotion. Although the cases were unfavourable, yet rapid union had taken place. The plan had been brought under his attention by Mr. Chiene.

*Penetration of Orbit by a Knitting Needle.*—Dr. KIRK DUNCAN demonstrated on a skull a curious injury which a little girl had received. By an accidental blow, a knitting needle had been driven through the orbit into the pharynx.

*Salivary Calculus.*—Dr. CHURCH showed a salivary calculus removed from a patient who had suffered from enlargement of the sub-maxillary and sublingual glands. On the third day, the calculus was discharged from the duct, opening on the right side of the *finnum lingue*.

*Cases of Aneurism.*—Dr. BYRON BRAMWELL read notes on some cases of aneurism. He had, within three years, treated six cases of aortic aneurism and one of the innominate artery; and he would also lay before the Society notes of three other cases. The treatment he had used was iodide of potassium, in large doses, according to the method advocated by Dr. G. W. Balfour of Edinburgh, and his results

bal been satisfactory. Of his cases, the most interesting were the following. An unmarried pitman consulted him at the Newcastle Infirmary on January 16th, 1875. A year and a half before, he had noticed sudden forcible pulsation in his right breast. He had suffered great pain three months before admission. Nine years ago, he contracted syphilis. There was a pulsating tumour at the upper part of the right side of the chest, close to the sternum. He had also unilateral sweating, dysphagia, hoarse voice, and a systolic basic murmur, with an accentuated second sound. Under half-drachm doses of iodide of potassium and the administration of morphia, he ultimately had great amelioration of his symptoms. The dysphagia, cough, and pain disappeared, and the pulsation became less. The unilateral sweating, however, continued. The second case was that of a sailor, with abdominal aneurism. Eighteen years ago, he contracted syphilis. There were great emaciation, severe pain, and difficulty in walking, from the flexure of the leg on the abdomen. Under half drachm doses of the iodide he made extraordinary improvement, and went out at his own request in thirty-five days. Four months after, he died from rupture in the left pleural cavity. In a third case, albuminuria was an intercurrent symptom; and, on *post mortem* examination, a large cicatrix was found in one kidney.—Dr. GRAINGER STEWART, after complimenting the author of the paper, said, in regard to the unilateral sweating and dilatation of the pupils, that he seen cases of the latter. He asked if Dr. Bramwell could give any explanation of the inequality in the radial pulses, as he had sometimes been puzzled to account for it in some of his cases. In the case of abdominal aneurism, with complete obstruction of the aorta, the kidney-lesions was probably due to the obstruction of one of the renal arteries. He had a case where the patient became exhausted, with slight symptoms of gastro-intestinal irritation. The small intestine was found congested, and with extravasations of blood and occlusion of the superior mesenteric artery. The obstruction seemed to have caused this, and, on referring to the literature, he found that it sometimes occurred. One point of interest was in regard to rupture. In a case where this occurred, the patient had symptoms of retro-pharyngeal abscess. There was fluctuation on palpation, and the question of opening it was mooted. However, this was not done, as it was extravasated blood.—Dr. BLACK, as a military surgeon, had seen many cases of aneurism; its causes were many. Dr. Bramwell had stated that syphilis was often present. Dr. Welsh had shown that syphilis was present in 48 per cent. of a series of cases; and some had even rated the proportion at 60 per cent. How syphilis produced it was not demonstrated, although small deposits in the arterial walls had been described. Rheumatism was said to have an influence, but in 18 per cent. there was no diathesis. Alcohol he believed to be one great cause, especially constant drinking or "soaking". The nature of the dress and the work seemed to be predisposing causes.—The PRESIDENT (Dr. SANDERS) mentioned that he had been consulted by a surgeon as to the propriety of opening, with antiseptic precautions, a swelling on the chest-wall. The swelling, on examination, proved to be aneurismal.—Dr. BRAMWELL said that in some of his cases the pupils varied in size. In the case of unilateral sweating, the pupil was small when it occurred, and the temperature behind the ear was one degree lower than on the opposite side. He had only to add that he could not explain the retardation of the radial pulse, and that few of his cases had syphilis.

#### PATHOLOGICAL AND CLINICAL SOCIETY OF GLASGOW.

FEBRUARY 12TH, 1878.

JOSEPH COATS, A.M.D., President, in the Chair.

*Ovarian Tumour.*—Dr. WILLIAM MACEWEN showed a large multilocular ovarian tumour, which he had removed from a woman aged 27. The symptoms were of one year's duration. There were many adhesions to the liver, omentum, etc., but none in the pelvis, where, however, the tumour was jammed in by its own growth. The pedicle was small, and on the left side, although the patient insisted on the fact that the first appearance of the growth had been on the right side. The operation was performed under ether; and after it some vomiting took place. The pedicle was ligatured; and, in spite of the complication of bronchitis and of the peculiar development of slight paralysis of the left arm and leg after the operation, the patient was making a very fair recovery.

*Genu Valgum.*—Dr. MACEWEN also showed a patient with genu valgum, whom he had brought before the Society at a previous meeting. Both legs had now been operated on by removal of a wedge-shaped piece of the femur above the joint; and they were now practically quite straight. At the last operation, a sharp chisel was used, which pre-

vented the trouble sometimes experienced from the separation of small bits of cancellated bone.—Dr. JAMES DUNLOP spoke of the great success of the case, which he regarded as one of the many triumphs of antiseptic surgery. Here was a severe operation near the knee, performed with safety and hardly any discharge.

*Paraffin Splints.*—Dr. MACEWEN showed also some paraffin splints. He had been using this material for splints for two years, and had found it act well. It set very quickly, retained its form well, and shed all discharge cleanly away from its surface. Paraffin varied as to its melting point, 113½ deg. to 130 deg. Fahr. being the usual points of fusion. It could be melted, therefore, in a bowl which was surrounded by hot water. He preferred the paraffin which melted at 113½ deg. The splints were very light and cheap (9d. per splint being an average); and, when no longer required, the paraffin could be melted in hot water and used over again. The chemical reaction of paraffin was quite neutral. At first, he brushed the paraffin over the bandages, but more recently he adopted the plan of rolling the bandages in the melted paraffin, and, when required, these were remelted in hot water and applied, a little melted paraffin being painted over the successive layers if required for extra strength. The paraffin was well suited for the body bandages in Sayre's spinal splints.—Mr. CLARK said the great objection to the use of paraffin was the danger of the softening of the material when near a fire or any source of heat. In one case, where he had used a glue bandage, non-union of a fracture had resulted from the melting of the glue near the fire.—Dr. DOUGALL said the name paraffin was derived from its want of affinity, neither acids nor alkalis uniting with it.

*Intra-thoracic Aneurism.*—Dr. JAMES DUNLOP showed a series of specimens illustrative of atheroma of the arch of the aorta, aneurism of the arch, and aneurism of the heart. All the specimens of aneurism of the heart which he had seen were on the right side. The whole of the specimens were from cases where sudden death under suspicious circumstances had led to medico-legal inquiry.—Dr. JOSEPH COATS said all the aneurisms of the heart which he had seen were on the left side.—Dr. DUNLOP showed for comparison a case of stab of the heart.—Dr. FOULIS alluded to a case which he had seen of rupture of the left ventricle without any aneurismal pouch; the muscular tissue of the heart was fatty.

*Putrefaction and Antiputrescents.*—Dr. DOUGALL showed specimens of fluids which he had kept for four years. They had been prepared, along with many others, to illustrate the phenomena of putrefaction and the action of various antiputrescents. 1. A specimen of beef-juice in a state of putrefaction; the bottle had been kept in the dark, and was glass-stoppered, and the fact that putrefaction still continued threw light on the state of sewer-fluids pent up in dark places. 2. A specimen of beef-juice, in which fermentation was induced by the addition of hydrochloric acid. If an albuminous fluid be divided into two parts, and one of these set aside, it putrefies; but if to the other part a vegetable or mineral acid be added, the putrefactive process is averted, and instead of it we have in a few days tufts of fungi, and after several months the reaction of albumen is quite lost in the fluid so treated. Contrasting this specimen with specimen No. 1, where putrefaction was still in progress after four years, Dr. Dougall said it showed that fermentation was a much quicker process than putrefaction. 3. A specimen of beef-juice, in which the putrefactive process had been arrested by the addition of hydrochloric acid. Two weeks after addition of the acid, the putrid odour had disappeared, and was replaced by a fragrant smell possibly akin to that of valeric acid. This odour had been retained by the specimen for four years. Dr. Dougall also showed various solutions to illustrate the theory of subsidence of germs or particles from the air; in one of these, boiled urine had been kept quite sweet and clear for four years by the simple precaution of plugging the neck of the flask with common cotton-wool, which acted as a filter to the particles in the air. This cotton-wool had been subjected to microscopical examination (with ½ lens), but only amorphous particles were seen. Dr. Dougall avoided entering into the various theories on the subject, and contented himself with showing the specimens.—Mr. W. J. FLEMING said the lapse of time in these experiments was of importance; he was inclined to think putrefaction was a phase of fermentation, and to agree with Pasteur's conclusions. He alluded also to Mr. Godlee's experiments on vaccinia as bearing out these views.—Dr. DOUGALL thought the process of putrefaction was so different from fermentation as to deserve a separate name. When one fluid remained clear and odourless and acid, but with a little fungus here and there, while a second fluid became turbid and putrid, he thought the difference was as great as between typhus and typhoid fevers, and that separate names should be given. If observers chose to call all changes in fluids fermentation, he could only object that simplicity was being gained at the expense of clearness.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 2ND, 1878.

THE DENTAL PRACTITIONERS' BILL.

WE stated last week that the hasty intervention of the Chairman of the Parliamentary Bills Committee of our Association, aided by the goodwill of Dr. Cameron of Glasgow, who very kindly, at a few hours' notice, at the request of Mr. Ernest Hart, took up the defence of medical and public interests in opposing this Bill, was effectual in arresting the progress of the Bill at the moment when it was about to pass its second reading unopposed, and with the support of the Government, owing apparently to the political inexperience of its avowed opponents, and their unwise reliance upon the supposed influence of some effusions of the pen which they had reprinted and scattered broadcast. The result of that inefficient mode of proceeding was, that the promoters of the Bill, who had taken the trouble, by one kind of statement or another, to remove the opposition of independent members and to secure the support of Mr. Cross, who represented Lord Sandon, were on the point of carrying this Bill through by a *coup de main* and while their opponents were napping. This having been prevented, however, and it having become apparent to the promoters of the Bill that it is perfectly hopeless, now that the plain objections to their measure have been disclosed, and that the Parliamentary opposition is in the hands of those who know how to organise it, they have resolved to give way on the subject of the objections made in the interests of the medical profession, and to strike out from the third clause the words "surgeon or dental surgeon", and to provide that legally qualified medical practitioners shall altogether be exempted from the working of the Act. This is so far satisfactory, and it meets in great measure the objections urged by our Parliamentary Bills Committee, except that it will, we think, be necessary to schedule the *Register*, in order to make it quite clear that the word "dentist" or "dental practitioner" only shall head the *Register*, and to see that the title of dental surgeon or surgeon dentist, so expunged from the third clause, shall not reappear in that or in any other part of the Bill, or in consequence of the working of the Bill.

There is, however, another objection to making immediate progress with the Bill. This Bill proposes to impose a complicated, extensive, and difficult series of duties on the General Medical Council. They are to make the *Register* of dentists and to keep it; to make all decisions as to putting dentists on the *Register* and to striking them off; they are to regulate the curriculum and to supervise examinations—in fact, to do everything for dentists which they now do for medical practitioners; but with this great difference, that the Bill, in the first place, has never been before the General Medical Council at all, so that they have had no opportunity of saying whether they understand those duties and are willing to accept them; and further, that the Council consists of, and is likely to consist, exclusively of medical practitioners, and has not a dentist upon it. In what way they are to decide what is the proper curriculum for dentists, what are the proper examinations, and what schools should be recognised, is not apparent; nor are there any professional dental advisers of the General Medical Council. The questions likely to arise as to the conduct of dentists, who may come on the *Register* and need to be put off again, will probably very often be of a complicated and disagreeable character. Medicine is a profession. Dentistry is largely a business; and these gentlemen sell all of them

teeth and gold plates, and alloyed gold plates and vulcanised plates, and use all sorts of materials for stopping, of various values. They are also very largely in the habit, some of them at least, of suing and being sued in County Courts, and, judging from the reports which are from time to time sent to us, dentists are sometimes charged with unfair representations as to the value of the goods which they supply, and sometimes with fraudulent misrepresentations. To adjudicate upon charges likely to be brought under such circumstances involves some knowledge of trade matters, as well as of professional matters; and if the General Medical Council have to undertake the tutelage and charge of dentists at large (and we by no means say that in no conceivable circumstances ought they to do so), they should at least have an opportunity of considering very carefully what is the proper machinery for carrying out their responsibility, and whether they are at present in a position to accept the responsibility involved under the conditions offered.

It does, therefore, appear to us most unusual, and quite contrary to the ordinary course of public business, that such a Bill should be pressed forward in the House of Commons without the General Medical Council having considered it. It is inconceivable to us that the Government should support such a course; and we should very much like to know what course Dr. Acland, the President of the General Medical Council, has taken in a matter which so deeply affects the Council and the profession. Has he protested against this Bill being proceeded with until the General Medical Council have seen it? If he have so protested, how is it that the Government has disregarded his protest, and that Lord Sandon, or his representative Mr. Cross, supported the second reading? Has Dr. Acland submitted it to a meeting either of the Executive Committee or of the Branch Council? If our Parliamentary Bills Committee were assured that the General Medical Council had had the opportunity of considering, and had approved the general machinery of the Bill, they would, we think, be inclined to withdraw further opposition, when their claim on behalf of the profession—that the title of surgeon should not be wrested from the profession—has been fully satisfied; but, until that information has been obtained, it is, we imagine, very unlikely that they will relinquish their opposition to the Bill. It will in this instance be their business to advance the interests of the General Medical Council, which are those of the profession, even against the Executive Council, if need be. It is hardly possible, however, to suppose that the President of the General Medical Council has given his approval to a Bill involving such great responsibilities to the Council, before the Bill has been considered by the Council at large; but in any case it would, we feel sure, be satisfactory to the profession to hear from Dr. Acland officially what view he has taken, and what course he has adopted, as President of the General Medical Council, in a matter which largely concerns the interests both of the Council and of the profession.

THE LOCAL GOVERNMENT BOARD AND COMBINED  
SANITARY DISTRICTS.

It is not surprising, considering the atmosphere of doubt which hangs over this subject, that the President of the Local Government Board should have been again called upon to explain to Parliament the attitude of his department on the combination of sanitary districts for the appointment of medical officers of health. In reply to a question from Colonel Naghten, whether he had considered the desirability, with a view to the better carrying out of the Public Health Act, especially with regard to the suppression of nuisances, of making it compulsory to appoint the medical officers of health in all cases for unions or other large areas, instead of, as is now sometimes the case, for parishes only, Mr. Selater-Booth is reported to have stated that he did not intend to propose any change in the law on that subject, but that the Local Government Board had always encouraged the combination of local authorities in respect to the appointment of these

officers, and it would continue to do so. It is somewhat significant that Colonel Naghten, a Hampshire member, and a neighbour of the President, as well as a supporter of the Government, should have invited this expression of policy on the part of the Local Government Board; and it is the more so, considering the fact that, with the exception of a small combination in the Christchurch district, the small area system was from the first adopted in Hampshire, the attempts of the then inspector of the district to obtain the division of the rural portion of the county into two large areas having signally failed. It may therefore, we think, be fairly inferred that if public opinion in Hampshire, as represented by one of the members of the county town, has come round to the side of the large appointments, there cannot be much doubt as to which way the current of opinion in the country generally is setting.

Whilst, however, it is somewhat reassuring to those who, like ourselves, have felt not a little puzzled by the course which the Local Government Board has pursued in regard to some of these appointments, to be informed that the Board is as much in favour of combined appointments as it has always been, it would have been more satisfactory if the President had given some indication of the way in which he proposes to encourage these appointments in the future. Hitherto, the encouragement which they have received from the Board has been of such a vacillating and feeble character, that a very small amount of repulsive action on the part of one or two parsimonious members of a combination has in most cases been sufficient to break up the combined district. It is true that the proportion of cases in which this falling away has taken place is a minority when compared with the whole number, and that in very few has the combination altogether fallen to pieces; still, the list of collapses is a sufficiently important one, including as it does such districts as Oxfordshire, Northamptonshire, and Huntingdonshire, with a considerable sprinkling of smaller areas, such as Taunton, Goole, Lytham, and some others which might be mentioned, to justify the inquiry whether the encouragement which Mr. Selater-Booth asserts that his Board has been in the habit of giving to the formation of large districts has been extended to maintaining them when they were formed; and if so, what is his explanation of the disintegration which the Board has allowed to take place in these cases? Of the few cases in which the original combinations have been augmented, we only know of one, that of Southam, in the Mid-Warwickshire district, in which this has been due to the compulsory action of the Local Government Board. In most instances where a sanitary authority has withdrawn from an existing combination, the Board has either made no opposition at all or it has been of the most perfunctory description.

Now, we have no intention of impugning the conduct of the authorities who have withdrawn from these combinations, for we have no means of knowing whether they had any justification for doing so on grounds of reasonable dissatisfaction with the way in which the work of the district had been done. Nor are we aware whether in any case in which this disintegration has taken place the person whose interests have been most directly affected by it, viz., the medical officer of health, has distinctly challenged the Local Government Board to hold an inquiry into the grounds of the withdrawal. It may be that this has been done in one or more cases, but if so, the fact has not come under public notice, and we are, therefore, driven to the conclusion that there must have been, in some of these cases at least, elements of weakness, either in the original constitution of the district or in its subsequent management, which to some extent justified the act of disunion. Indeed, looking at the haphazard and disjointed way in which these large districts generally were first organised, and to the fact that the tenure of office which was guaranteed was only of a limited description, and, therefore, not calculated to tempt a large number of first-class men into the field of competition for them, we should not have

been surprised if the cases of dissociation had been more numerous than they have been; and we think that it says something in favour of the tact and efficiency with which the officers to combined districts have, on the whole, done their work, that the tenants of office in most of the larger districts have been re-elected on the same terms as those on which they were first appointed; and that in some cases the desire was expressed that the appointment should be made of a permanent nature. Up to the present time, however, the Local Government Board has not only not encouraged permanent appointments, but has absolutely refused to sanction them. The only intelligible explanation of a course which is so diametrically opposed both to the practice of the Board itself in regard to poor-law appointments, and to the experience and opinions of all competent authorities on this matter, is, we apprehend, to be found in the forecast which the Board has for some time had of the probable organisation of county boards, which has at length become a Government measure, and in the assumption that in view of such a contingency, and of the propriety of putting the appointment of officers of health for county areas under such boards, it would be inexpedient to create permanent vested interests which might to some extent conflict with such a policy. We shall soon learn, either from the Bill now being printed or from the modifications which it may receive as it passes through Parliament, whether this supposition is well founded or not. It will be a singular instance of short-sightedness if these boards, when they are constituted, are to be invested with the appointment of coroners, as the Bill, we believe, proposes, and the opportunity is neglected of placing the sanitary supervision of their districts also in their hands, and of thus bringing the sanitary and judicial systems of inquiry, as represented respectively by the medical officer of health and the coroner, into a relationship with one another, which would be eminently beneficial to the public interests. So far as the present position of medical officers of large areas is concerned, nothing could well be more unsatisfactory. They are deprived of that independence which a fixed tenure of office would give them; they are in no relationship either to the poor-law medical officers on the one hand or to the medical staff of the Local Government Board on the other; they have no control over the officials who work under them, nor are they themselves under such supervision as a properly organised system would provide. In such a state of things as this, of which the Local Government Board has full cognisance, it is scarcely credible that the President should limit his statement of the future policy of the Board in regard to these appointments to a meagre promise of encouragement, except upon the supposition that he has in his mind's eye a more excellent way of encouraging them than that which he has hitherto adopted.

#### LIFE-INSURANCE AND BURIAL CLUB MURDER.

IN a trial for murder which recently took place at the Chester Winter Assizes, the evidence brought to light the defects in our present method of detecting and tracing crime. A woman of the name of Heesom was tried and convicted of the murder of her infant child, Sarah, by the administration of arsenic. The deceased Sarah Heesom was born in October 1876, and was proved to have been a fine healthy child. In October last, about midday, the child was seized with violent vomiting and purging, and it died the same evening in a fit of convulsions. As the child was teething, a medical man who was called in certified that the cause of death was convulsions from teething, *i. e.*, natural causes.

This case of murder by poison would have been passed over but for the fact that the prisoner's mother, Mrs. Symes, who had come to live with her, was taken suddenly ill the day after her arrival with vomiting, purging, cramps, and other symptoms like those observed in the child, and she died in a few hours. The suddenness of death excited suspicion in this case; and, on a *post mortem* examination and analysis, it was found that the woman had died from the effects of arsenic, seven

grains of that poison being found in her body. The bodies of the child Sarah Heesom and of Lydia Johnson, another child of the prisoner's, who had died in March 1876, were exhumed and examined. Arsenic was found in them, and the convulsions from which Sarah Heesom was certified to have died were thus proved to have been caused by arsenic and not by teething. The arsenic found in the stomachs was not mixed with any colouring matter, and there was evidence that about the date of these acts of murder the prisoner had had white arsenic in her possession. The evidence further showed that the prisoner had insured the lives of her mother and the two children in some assurance society, and that she was paid upon the three deaths a sum of money amounting altogether to £21. There was also proof that the deceased persons were entered in two burial clubs.

These cases demonstrate that the present mode of registering the causes of death is very defective. There was surely enough in the case of the infant to excite strong suspicion of the cause. Fatal convulsions from teething are not preceded by well-marked symptoms of irritant poisoning such as were observed in this case. There is not a sudden access of vomiting, purging, and severe pain affecting the stomach and bowels, followed by death in a few hours; and it is not enough, on these occasions, to assign the cause of death to "convulsions" without tracing the convulsions to their probable source. In narcotic as well as in irritant poisoning among infants and children, convulsions are frequently observed. Under a proper system of registering the causes of death, this would have been a case reserved for inquiry. No certificate would have been given in the absence of a *post mortem* examination.

Another point for observation is—How did it happen that no inquest was held on the body of this child? There must have been a want of due diligence on the part of the coroner and his officer. Had it been the case of some aged person, dying suddenly of apoplexy, under no suspicious circumstances, there would probably have been the formality of an unnecessary inquest; but where two children die in a few hours, in the same house, under well-marked symptoms of irritant poisoning, the cases are allowed to pass without observation; and it is only the sudden death of the grandmother, a month later, which led to the discovery of these acts of murder. The coroner's inquest, as it is at present conducted, is insufficient to initiate proceedings in these cases of secret poisoning.

Another fact to be noticed is, that the provisions of the Act regulating the sale of arsenicals are easily evaded. As sold to the public, arsenic must be coloured either with indigo or with soot. In the body of the grandmother, there were found seven grains, in that of Lydia Johnson fifteen grains, and in the body of the infant one grain and a quarter. There was no colouring matter in any one of them, and it was obvious that the poison had been administered as white arsenic.

These cases clearly show the necessity for greater care on the part of medical men in certifying causes of death in children, and for greater watchfulness on the part of coroners where several deaths occur in the same family under similar symptoms.

SEVERAL surgeons of the Stafford House Committee received, from the Turkish authorities at Constantinople, military medals of merit.

ACCORDING to the *Pester Medicinische Presse*, Professor Hyrtl, who has for some years retired from public life and has been residing near Vienna, has lately completed a lexicon of terms used in medicine.

*A propos* of the discussion on the Lost School at Oxford, and the severance which has there been effected by the positive and negative action of Dr. Acland, Dr. Rolleston, and others, between the teaching of natural science, preliminary and collateral to medicine, and the study of medicine itself, we publish in another column a valuable and weighty letter from Mr. Savory. This letter is of great importance at this moment, not only from the authority and philosophic power of thought of the writer, but from the obvious and direct bearing upon the

assumptions which have been made by those who propose to support the supposition of the Oxford Medical School that London teaching is something for which academic teaching in Oxford should be sacrificed, and who are disposed to concur with Dr. Acland that London medical schools are of unsurpassable excellence; so that Oxford ought to retire from the competition without even an effort to show what philosophic and complete medical teaching should be.

WE see with great regret the various letters which have appeared in the papers, intimating that placards have been posted at the hospitals calling upon medical students to assemble in gangs to give traitors a lesson in patriotism. We have already expressed the opinion, in which we believe the authorities will agree, that, while medical students have a right to take their place as citizens in the expression of political opinions, it is extremely undesirable that they should, in their quality of medical students, and in any way associated with hospitals and medical schools, in bodies, take part in political disturbances; and it is much to be desired that hospital authorities will be vigilant in preventing the posting of any such placards, and will, moreover, use their moral influence in preventing their students from taking part in riotous demonstrations of the kind on behalf of any party whatever.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE annual general meeting of this Society will be held this evening (Friday) at 8 P.M. The following gentlemen have been nominated as the officers and Council for the year 1878-1879. [An asterisk is prefixed to the names of those who have not held similar offices during the past year.] *President:* Charles West, M.D. *Vice-Presidents:* William Wood, M.D.; \*Richard Quain, M.D., F.R.S.; John Cooper Forster, Esq.; John Wood, Esq., F.R.S. *Treasurers:* William Wegg, M.D.; John Birkett, Esq. *Secretaries:* \*James Andrew, M.D.; \*Timothy Holmes, Esq. *Librarians:* \*George Johnson, M.D., F.R.S.; \*William S. Savory, Esq., F.R.S. *Other Members of Council:* Robert Barnes, M.D.; William C. Begley, M.D.; \*C. Handfield Jones, M.B., F.R.S.; \*Octavius Sturges, M.D.; \*E. Symes Thompson, M.D.; \*W. Morratt Baker, Esq.; \*Henry H. Hayward, Esq.; \*M. Berkeley Hill, Esq.; \*Arthur B. R. Myers, Esq.; \*Robert J. Spitta, M.D.

#### THE MIDLAND MEDICAL INSTITUTE, BIRMINGHAM.

IT is some time now since much has been heard of the above proposed "Institute"; but we are glad to be informed by a Birmingham correspondent that it is now on so solid a foundation that it is nearly absolutely certain that an excellent building will be raised in a most convenient and central situation, viz., New Edmond Street; the portion of land proposed to be built upon being, it is stated, now fixed; and the plans for the building in a very forward state, ready to be submitted to the Building Committee and the members. The public, though at present few in number, who have already been asked for pecuniary assistance, have generously responded. We understand that the annual meeting is to be held about the second or third week in March, when a scheme or two for raising more money for the building will be proposed for adoption by the members, which, if carried (following the example of the Law Society in Birmingham), will, with some further assistance from the public, raise funds sufficient to give substantial existence to what, we believe, will be a most useful and creditable undertaking. Liverpool has failed for many years to obtain such an institute or library, and it is only lately that rich Manchester has succeeded in doing so in a satisfactory manner. We have reason, therefore, to congratulate ourselves that the Birmingham Medical Institute is in so hopeful a position.

#### DEATH FROM CHLOROFORM.

THE particulars of the death from chloroform which occurred at the Northern Hospital, Liverpool, recently were, we are informed, as follows. The patient, an apparently healthy man, sustained an injury to his right eyeball on January 26th, and was admitted under Dr. Campbell. Extirpation of the eyeball was determined upon, and chloroform

administered. Skinner's inhaler was used. The administration was commenced with rather less than a drachm of chloroform, the patient inhaling it quietly for three or four minutes; the stage of excitement was then entered, lasting two or three minutes, during which the patient struggled violently and talked incoherently. Then he became quiet, the conjunctivæ being insensible to touch. The pupil at this time was much contracted. Muscular relaxation was not complete, the jaws being firmly clenched; breathing was going on well; the pulse was good. At this point, the inhaler was removed, about three drachms of chloroform having been used, the time being from eight to ten minutes. The speculum was being introduced between the lids, when the breathing was noticed suddenly to stop, the lips were slightly livid, the pulse was going: the chest was immediately pressed upon. The pulse, which was again felt almost immediately, was stopped. Artificial respiration by Silvester's method, also by Sayre's method, was kept up for half-an-hour; and, although the patient breathed a few times spontaneously afterwards, neither the pulse nor heart-beat was again felt. Galvanism, inversion, dashing of iced water on the face and chest, and ice in the rectum, were tried, but were of no avail. At the *post mortem* examination, the body was found to be well nourished. There was a wound of the right eye, and two large blisters, one on the arm and the other on the shoulder, due to hypodermic injection of ammonia. The left pupil was not widely dilated. The pericardium contained two drachms of serum. The heart was flaccid; the left side contained two ounces of fluid blood; the right about the same quantity, also fluid. The tricuspid valve admitted four fingers; the other valves were normal. The orifices of the coronary arteries were dilated. There was commencing atheroma of the aorta behind the aortic valves. The heart was rather pale; and the microscope showed slight fatty degeneration. It weighed twelve ounces. There were slight pleuritic adhesions on the left side. No fluid was found in the pleura. There was considerable oedema and emphysema of both lungs; congestion was not marked. The liver was very much congested, but healthy. The kidneys together weighed twelve ounces. They were very much congested, almost like scarlatinal kidneys, slightly granular. The bladder was contracted, almost empty. There were no casts in the urine. There was a considerable increase of subarachnoid fluid; the membranes of the brain stripped off readily. On section of the brain, the veins were found markedly congested.

#### SANITATION IN THE ISLE OF WIGHT.

THERE is probably no part of the British Isles in which sanitary reputation is so essentially necessary to prosperity as in the Isle of Wight, and there is certainly no part of Great Britain which stands higher in popular estimation for natural hygienic advantages. It is not unnatural, therefore, that the mortality statistics of the island should call for critical examination, especially with a view to determine how far these natural advantages are being fostered and protected by intelligent sanitary organisation. The area of the Isle of Wight consists of 93,241 acres, including 123 of inland water. At the first national census in 1801, the enumerated population of the island was 22,097 persons; while at each subsequent decennial census the population showed a marked increase, and amounted in 1871 to 66,219 persons, or very nearly three times the population enumerated in 1801. Assuming that the rate of increase of population in the island since 1871 has increased at the same rate as that which prevailed between 1861 and 1871, the population in the middle of this year may be estimated at 75,312 persons. The annual death rate per 1,000 in the island was equal to 17 per 1,000 in each of the decades ending in 1850, 1860, and 1870, and therefore averaged 17 per 1,000 during the thirty years 1841-70. During the past seven years of the current decade, the annual death-rate has averaged 16.5 per 1,000, showing a slight decline from the average rate in the preceding thirty years; the lowest death-rate in the past seven years was 15.1 in 1873, and the highest 18.2 in 1875. For almost any other place than the Isle of Wight, these death-rates might be accepted as evidence of satisfactory sanitary condition; but, while

it is not easy to say how low the death-rate in the Isle of Wight might be brought under perfect sanitary organisation, there is no difficulty in pronouncing unhesitatingly that, having due regard to the natural advantages of the climate and situation, this death-rate, comparatively low as it is, is excessive. During the seven years 1871-7, no fewer than 924 deaths were referred to the seven principal zymotic diseases, including small-pox, measles, scarlet fever, diphtheria, whooping-cough, fever, and diarrhoea: these 924 deaths were equal to an average annual rate of 1.9 per 1,000 persons estimated to be living in the borough; and it is unsatisfactory to note that this zymotic fatality has somewhat increased in recent years. Infant mortality in the island, measured by the proportion of deaths under one year of age to births registered, averaged 103 per 1,000 in the past seven years, and ranged between 128 in 1875 and 77 in 1876; infant mortality in the island should not average more than 80 per 1,000. It follows, therefore, that better sanitary organisation ought to have saved during the past seven years, not only more than three hundred infants who died under one year of age, but also a large proportion of the 924 deaths referred to the seven principal zymotic diseases. It may be useful, therefore, to glance briefly at the sanitary organisation of the island. Under the provisions of the Public Health Act of 1872, the island contains eight urban and one rural sanitary districts; and, as the Poor-law guardians of the Isle of Wight have divided the health responsibilities of the rural sanitary district among their nine district medical officers, there are no fewer than seventeen medical officers of health in the island. These seventeen medical officers of health have, for the most part, purely nominal salaries, ranging upwards from £8 15s., paid to the Medical Officer for East Cowes; the largest salary is £80, paid to the Medical Officer of the Urban Sanitary District of Ryde. The Rural Sanitary Authority of the Isle of Wight pay to their nine district medical officers an aggregate salary of £290. Thus, while the Isle of Wight has a medical officer of health for each 4,000 of its inhabitants, all are engaged in private practice. The aggregate salaries of the seventeen medical officers of health amount, however, to nearly £600 *per annum*; so that, if the numerous small sanitary districts were combined under the provisions of the Public Health Act of 1875, it would be easy, with scarcely an increased expense, to secure the services of a specially qualified professor of public hygiene, who, debarred from private practice, would be able to devote his whole time to the task of improving the sanitary reputation of the Isle of Wight. Its insular position and the special advantages of climate, as well as the special constitution of its population, should, with more perfect sanitary organisation, soon render the present waste of life from zymotic diseases a thing of the past. Joint hospital accommodation for the isolation of cases of infectious diseases should be one of the first results of a combination of the numerous sanitary districts. Anyway, the present large proportion of zymotic fatality in the Isle of Wight should engage the serious attention of those most interested in the prosperity of the island as a favourite health-resort.

#### THE CONTAGIOUS DISEASES ACTS AND THE HEALTH OF THE ARMY.

THE Army Medical Department Report for the year 1876, recently published, contains figures which should not be lost sight of by those anxious to inform themselves as to the true effect of the Contagious Diseases Acts upon the prevalence of venereal disease in the army. It cannot be said that this last report contains figures that are in any way new in their bearing upon this subject; but the addition of each new year's figures widens the field of observation, and adds to the value of the comparison of the rates of admission to hospital for these diseases at stations under and not under the provisions of the Contagious Diseases Acts. The opponents of these Acts are so reckless in their denial of the existence of any evidence of beneficial sanitary effect produced by them, that it is necessary from time to time to call attention to such facts as those contained in the Army Medical Report before us. During 1876, at fourteen stations under the Acts, the average annual strength of the troops was 48,620, among whom admis-

sions for primary venereal sores averaged 33 per 1,000, while the admissions for gonorrhoea were 68 per 1,000. Thus, for both forms of disease, the admissions were equal to 50.5 per 1,000. On the other hand, at fourteen other stations not under the Acts, the average annual strength of the troops was 18,790, among whom the ratio of admissions equalled 82 per 1,000 for primary venereal sores and 89 for gonorrhoea. Thus, at the stations not under the Acts, the average rate of admission from both forms of disease was 85.5 per 1,000, against 50.5 at the stations under the Acts. At the fourteen stations under the Acts, the highest rates of admission for primary sores were 41 and 47 respectively at Windsor and Aldershot; whereas, at the fourteen stations not under the Acts, the rates of admission for these diseases ranged upwards to 113 in Manchester, 119 in Sheffield, and 145 in London. So, with regard to the rates from gonorrhoea, the highest rate among the fourteen stations under the Acts was 93 at Devonport and Plymouth; whereas, at the fourteen stations not under the Acts, the gonorrhoea-rate ranged upwards to 105 in Preston, 113 in Dublin, and 152 in Manchester. A comparative table gives the rates of admissions from primary sores at each of these twenty-eight stations in each of the ten years 1867-76. This table clearly shows that the rate of admission from this disease at the stations under the Acts was in many years less than half that which prevailed at the stations not under the Acts. As, however, the average rates in each year in the aggregates of the fourteen stations under the Acts, and of the fourteen stations not under the Acts, are not given in the table, it is not possible to compare the proportional decline in the rates of admission during these ten years in the two groups of stations. This is to be regretted, as the opponents of the Acts assert that the decline in the prevalence of venereal diseases has been as large where the Acts have never been in operation as at the stations under the Acts. This assertion is disproved by the facts in this Army Medical Report; but the tables are not framed in such a way as to show satisfactorily the actual rate of disease in each of the two groups. It is pointed out that, in the group of fourteen stations under the Acts, the average rate of admissions from primary sores during 1876 showed a decline of 2 per 1,000 from the rate in 1875; whereas, in the contrasted group of fourteen stations not under the Acts, the rate in 1876 exceeded the rate in the preceding year by 3 by 1,000. It will only be necessary to allude to one other fact brought out by these figures in this Army Medical Report, and affording evidence of the influence of the Contagious Diseases Acts upon the prevalence of venereal diseases in the army. We have already pointed out that, among an average annual strength of 48,620 troops at the fourteen stations under the Acts, the rate of admissions for primary sores was equal to 33 per 1,000 in 1876. It is also shown that the rate among 38,073 troops at all other stations averaged 63 per 1,000, and was as nearly as possible twice as high as at the protected stations. It is further shown that the rate of admissions from gonorrhoea in 1876 averaged 68 per 1,000 at the fourteen protected stations, whereas at all the other stations it averaged 89 per 1,000. As is well known, the effect of the Acts upon the admissions for primary sores is far more marked than upon the admissions for gonorrhoea, although the rates from both forms of disease were in 1876 markedly lower in the protected than in the unprotected stations, being equal to 101 and 143 per 1,000 respectively. If the opponents of the Acts are to maintain their persistent denial of the beneficial effect of the Acts upon the prevalence of venereal diseases, it is incumbent upon them to furnish a more reasonable explanation of the comparatively low rates from these diseases prevailing among the troops at the protected stations, than that supplied by the provisions of the Acts themselves.

#### THE METROPOLITAN AND NATIONAL NURSING ASSOCIATION.

At a meeting of this Association, held at Grosvenor House, under the presidency of the Duke of Westminster, the report showed that, in four districts of the metropolis, namely, in Bloomsbury, Holloway and Islington, Paddington and Marylebone, and East London, the

committee were working, and hoped ere long to be able to form a fifth district in Lambeth. They had not the means of extending their organisation beyond the limits of the metropolis, but the committee wished it to be known that they would always be ready to consider any well-digested scheme for the affiliation of the existing district nursing institutions in the country. No actual steps had been taken towards establishing a training school for nurses; but, in the meantime, nurses are trained for the association at St. Thomas's Hospital by the Nightingale Training Fund. In order to carry on the five homes of the association during the present year, a sum of £5,000 was required, whilst the present subscription list amounted to less than £2,000. A letter was read from Miss Florence Nightingale, supporting the objects of the association.

#### LEPROSY IN SPAIN.

THE Spanish Government has ordered statistics of leprosy to be collected. In a medical report presented to the Governor of Valencia, it is stated that that province contained forty-five lepers, but it was difficult to obtain detailed information, the disease being concealed or disguised under a variety of names.

#### ALLEGED MANSLAUGHTER.

ELLEN WALKER, a midwife, has been committed for trial by Mr. A. Bode of Aylesbury, on a charge of causing the death of Jane Tomes, twenty-seven years of age. It appeared that prisoner was engaged to attend the deceased in her confinement, and, according to the evidence of persons who were in the house at the time, she treated the woman badly. Dr. H. G. Lee and Mr. Geely considered it a case in which a midwife should not have acted alone, and described the prisoner's conduct as most unjustifiable under any circumstances. In reply to the charge, prisoner said she did the best she could for the woman.

#### SMALL-POX AT HARWICH.

WE learn, in reference to the outbreak of small-pox at Harwich, that a fresh case was admitted to the temporary hospital on February 21st—an unvaccinated patient, thirty years of age. As might have been foreseen, it has proved of the confluent type. This case came from Dovercourt. No other new case was brought under the care of our correspondent this last week. At present, there are only eight cases in hospital, seven of whom are nearly convalescent. There is, therefore, every reason to hope that the epidemic is at an end. Of course, there is still the possibility of isolated cases occurring; but, with the means at the disposal of the authorities, it is not likely that the disease will again spread.

#### MEDICAL DEFENCE.

A FEW weeks ago, we called attention to the fact that in Liverpool an advertising obscene quack was assisted by a duly registered practitioner, whose name was boldly displayed on a brass plate beneath that of the quack, with the title of "surgeon" below. We are now informed that his name has been removed since our notice was reproduced in the local papers. We now learn, much to our regret, that another name appears on the door of the quack, with the title of "surgeon" below. The Christian name is not given. The surname, though peculiar, is not uncommon, there being five practitioners bearing it in the London department of the *Medical Directory*, thirteen in the Provincial, and one in Ireland. Thus within the space of two months three different registered practitioners have been induced to act as partners or assistants to this person, aided by the apathy which has always protected his fraternity. The matter will again form the subject of a complaint to the Medical Council, and we trust with some effect. The words of the Act are: "If any registered medical practitioner.....shall, after due inquiry, be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they think fit, direct the registrar to erase the name of such medical practitioner from the Register." That the conduct we have described is infamous in the intended sense

of the word cannot be disputed; and that a severe example should be made is equally plain. It is much to be regretted that there is no public prosecutor, and that the General Medical Council is unable to act in such matters until set in motion by private individuals. We have before expressed the opinion that it is very desirable that there should be a "Defence Committee" attached to the Council of each Branch of the British Medical Association, capable of taking the initiative in such breaches of the law and attacks upon professional honour and public safety. The East York and North Lincoln Branch passed resolutions inviting the Association at its Sheffield meeting to take measures for affording central support to such local Defence Committees. The Association, if we remember aright, remitted the question to the Committee of Council; and the result up to this time has been negative. We do not remember whether the Committee of Council has reported to the subsequent meetings of the Association on the subject; nor have we seen any statement or summary of argument in favour of or against some more organised effort within the Association to protect professional interests, in the manner which the Medical Defence Association has found to be practicable. Meantime, however, such examples as these at Liverpool, which are typical of what is constantly occurring all over the country, seem to show that, in the absence of a public prosecutor and the enforced quiescence of the General Medical Council, local Committees are much needed to put a stop to the open frauds of obscene quacks, and in some cases to the discreditable connivance of registered practitioners with their practices.

#### TREATMENT OF LUNATICS.

It is reassuring to know that the lunatic who shot at the Master of the Rolls did not put a bullet in his pistol. We have, however, often wondered since whether this is the same gentleman who applied, a week before, to Mr. Vaughan, at Bow Street, for advice and assistance, and who explained that "he had been the subject of a conspiracy for seven times seven years, and now he felt strange draughts of wind blow into his mouth and send him to sleep, and that that was a part of it". Whereupon, Mr. Vaughan said that "he should now and again take a walk into the country. It, no doubt, would do him good." The applicant quietly left the court, remarking "that his means were not always equal to his wishes". It may be suggested to magistrates that they are not altogether right in sending, as they constantly do, into the world at large, lunatic persons who come under their notice. No one who has looked down the list of criminal trials and inquests lately can have failed to have noticed the astonishingly large number of lunatics at large who have committed acts of violence in all parts of the kingdom, in many instances with murderous results. The Select Committee of the House of Commons, which has been sitting all last session, has, we believe, failed to discover any single instance in which a sane person has been unjustly incarcerated; every day, however, affords evidence that there are a large number of dangerous lunatics at large, who ought to be incarcerated in fairness to themselves and in justice to their friends or enemies.

#### DALLINGER ON EQUIVOCAL GENERATION.

THE Rev. W. H. Dallinger delivered a lecture at the London Institution on Monday evening on spontaneous generation. There were, he said, many admirers of the theory of evolution who held that, unless spontaneous generation were admitted, the theory was incomplete. Just as in water there is the potentiality of forming crystalline patterns in snow and ice, so they hold that in organic matter generally there is the potentiality of forming protoplasm. No living structure contains any known element that is not met with in the inorganic world, and the only chemical difference known is in the combinations of the elements. But the lecturer urged that evolution and spontaneous generation were two distinct questions, that need very accurate study apart. The developmental progression of all living forms from simple protoplasm is a very different question from whether living protoplasm can be spon-

aneously evolved from the inorganic world. For himself, if facts were brought forward to support spontaneous generation, he should be bound, were they valid facts, to accept the theory. He had, however, devoted much labour and the time of years, to the rigid investigation of some of the facts that bear upon the question, and these he would describe. It had seemed to him, in studying what had been written, that there were two lines of work that needed following out very closely. One was a series of thermal experiments, to determine with exactness what is the "death-point of an organism, or a germ". The other was to watch the life-history of some forms of monads, and see if they did reproduce. It was this second line he had taken up. The most carefully conducted experiments of the first group had led to the conclusion that if all germs are excluded from septic liquids no life appears, while his experiments had conclusively shown that monads do reproduce from parental products, for the life-history of successive generations had been watched. The natural inference seemed to be that monads originate only from previously existing monads; and if this were true to them, it was not improbable that observations conducted with equal care will show the same with regard to bacteria.

#### CONTAGIOUS DISEASES IN THE NAVY.

SOME time since, a parliamentary return bearing the above title was moved for by Sir Harcourt Johnstone. It has since been printed by order of the House of Commons, and issued as a parliamentary paper. In noticing the statistics contained in this return in our issue of the 22nd of December last, we surmised that Sir Harcourt Johnstone "could never have anticipated that the return he moved for would afford evidence so crushing to the assertions of the advocates of repeal" of the Contagious Diseases Acts. It would appear, however, from a circular letter with which, together with our contemporaries, we have been favoured by Sir Harcourt Johnstone, that he fails to see the true bearing of the figures in his return, and that he especially objects to a paragraph in the last official Report on the Health of the Navy, in which reference is made to his return in the following words: "The advantages of the Contagious Diseases Acts are shown by a comparison of the five ports in which these are in force, as compared with other five where they do not prevail." It may be useful to point out one or two of the grounds on which we entirely dissent from the view Sir Harcourt Johnstone appears to have adopted of the bearing of the figures in his return. It is stated that, in the five protected ports, the rate of contagious diseases in the navy was 31.23 per 1,000 higher in the five years 1871-5 than in the five preceding years; that the severity of the disease has also increased, as evidenced by a higher rate of cases of secondary disease; that the most common form of disease has more than doubled; and that the only apparent advantage of the Acts is a decrease of 4.21 per 1,000 in the rate of cases of primary disease, which is, it is asserted, unimportant in character. With regard to the increase of the rate from all forms of disease, it is evident that this is almost entirely due to the marked increase in the cases of gonorrhoea, which is not confined, as might be inferred by Sir Harcourt Johnstone's statement, to the protected ports, but is almost as great in the ports which have never been under the Acts. It may be admitted that the Acts do not appear to exercise any beneficial effect upon the gonorrhoea-rate; but there is absolutely no evidence of what is asserted by the opponents of the Acts, that the increase in this rate is due to the operation of the Acts, as a similar increase is observed at the ports in which the Acts have never been in force. The real causes of this apparent increase of gonorrhoea are probably those assigned by the Director-General of the Medical Department; namely, that it is due "to the greater number of cases recorded, rather than to any real increase of disease". The small increase in the rate from secondary disease in the protected ports between 1866-70 and 1871-5 is referred to as a proof of the baneful influence of the Acts, while no mention is made of the fact that identically the same proportional increase in the rate from secondary disease between the same periods occurred at the ports which have never

been under the operation of the Acts. So much for the unwarrantable assertion that the Acts have caused an increase in the rates from gonorrhoea and secondary syphilis. On the other hand, with reference to the assertion that the figures in Sir Harcourt Johnstone's return afford conclusive evidence of the beneficial effects of the Acts upon the health of the navy, we cannot, it appears to us, do better than quote a few figures from our notice of the return in our issue of December 22nd. In the five ports brought under the Acts, the average ratio of cases of primary and secondary syphilis declined from 75.0 per 1,000 in 1860-3 to 43.6 in 1871-5; while in the five ports not brought under the Acts the average ratio of cases increased from 70.1 in 1860-3 to 96.4 in 1871-5. Thus the rate from these forms of disease decreased 42 per cent. in the ports under the Acts, while it increased 37.6 per cent. in the ports not under the Acts. Further, the return shows that in 1860-3, before the Acts were passed, the ratio of disease was somewhat lower in the five ports that have not been brought under the Acts than it was in the other five ports subsequently brought under the Acts. Twelve years later, however, in 1871-5, the ratio of primary and secondary syphilis did not exceed 43.6 per 1,000 in the five ports under the Acts; while it was 96.4, or more than thrice as high, in the five ports which remained, as they were in 1860-3, unprotected. In conclusion, it appears to us, as we expressed it in the article above quoted, that "the marked decline in the cases of syphilis (primary and secondary) at the protected ports, concurrently with as strongly marked an increase at the unprotected ports, is unaccountable, unless attributed to the beneficial effects of the Acts". Judged by their unsuccessful attempts to saddle the Acts with the large increase of the rate from gonorrhoea, and with the small increase in the rate from secondary syphilis (which is as marked at the unprotected as at the protected ports), it will severely test the ingenuity of the opponents of the Acts to explain away the figures supplied by Sir Harcourt Johnstone's return, which support the assertion that the Contagious Diseases Acts have proved beneficial to the health of the navy.

#### A SUCCESSFUL GASTROSTOMY.

DR. F. TRENDELENBURG reports in the *Wiener Med. Presse* another successful case of gastrostomy to be added to the hitherto unique case of Verneuil. A boy aged seven years, the subject of impassable stricture of the oesophagus from swallowing caustic potash, had fallen into extreme marasmus. Gastrostomy was performed without bad effects, and two days afterwards nourishment could be introduced into the stomach through the small resulting gastric fistula. A small drainage-tube of the thickness of the little finger was introduced into the fistula, into which was passed a thicker glass tube having attached to it an elastic gum catheter reaching to the mouth. When the boy wants to eat, he chews his food and expels the masticated mass through the tube into the stomach. Four months after the operation, the boy's weight had increased by a fourth.

#### WATER-SUPPLY.

THE results of the investigations of Mr. Wigner on the supply of water to seaside resorts, published in the *Sanitary Record*, appear to be as follows. Amongst the best waters tested are those received from Exmouth, Kingswear, Ryde, Paignton, Weymouth, Plymouth, Portsmouth, and Ventnor; and these are followed very closely by Teignmouth, Lynton, St. Ives, Dartmouth, Penzance, Gosport, West Cowes, Devonport, East Cowes, and Ilfracombe. They may all be ranked as first-class waters; and it is satisfactory to know that about three hundred thousand residents, and probably nearly five hundred thousand visitors, or about eight hundred thousand persons in all, are supplied with water of excellent quality. Eleven other places—namely, Seaton, Sidmouth, Shanklin, Brixham, Clifton, Portishead, Westward Ho, Falmouth, Sandown, Torquay, and Weston-super-Mare—are supplied with water which must be considered as second class. The defects in these waters, however, are not very serious, and in almost every case are due either to imperfect storage or to imperfect

filtration. The only places where the water-supply may be characterised as third class are where there is no public supply, but the water is derived from pumps and wells, or direct from the river. Amongst these, we feel it a duty to mention Dawlish, Freshwater, Yarmouth (Isle of Wight), Kingskerswell, Seaton, and Paynton. The water at Aldeburgh, in Suffolk, is described as excessively saline and otherwise contaminated, as well as swarming with animalculæ. Rottingdean, that prettily situated village near Brighton, is credited with having the most impure water of the two hundred and thirty samples analysed by Mr. Wigner in the course of his investigations. The Isle of Man sends two first-rate samples from Douglas and Ramsay. This series of investigations is about to be published in a convenient form for reference.

#### PRESERVED VEGETABLES.

PROFESSOR ATTFIELD, in an exhaustive article recently published in pamphlet form, gives the results of analyses of samples of preserved carrots, potatoes, and mixed vegetables, taken from the residual stores of the *Alert* and *Discovery*, made at the request of the Chairman of the Admiralty Committee appointed to consider the causes of the outbreaks of scurvy in the recent Arctic expedition. These results are briefly as follows. 1. The preserved carrots were of good quality. 2. The preserved potatoes were of good quality. 3. The preserved cabbage was deficient in saline constituents. 4. The specimen of preserved mixed vegetables was probably somewhat deficient in saline substances. Whether or not these conclusions may be applied to similar preserved vegetables supplied to the public cannot be definitely decided until more analyses have been published. Dr. Attfield says, however, that it is evident that, in the most important matters of colour and general appearance, preserved vegetables can be sent to the table in a condition very closely resembling the fresh articles. Properly soaked, dried vegetables also reabsorb almost their normal proportions of water, and become normally tender and juicy. After directing the exclusion of the stalks and thick midribs in drying cabbage, to prevent loss of juice and retention of mere fibre, he says the taste and aroma remaining in the preserved article will probably satisfy the nose and palate of those who really desire such vegetable food and cannot obtain it in the fresh condition; and, on the whole, he is of opinion that preserved vegetable substances, roots, and fruits deserve the already large confidence placed in them by the public.

#### SCOTLAND.

THE Glasgow Town Council have placed the Parliamentary Road Hospital at the disposal of the directors of the Royal Infirmary, for the treatment of all the applicants for admission into the city hospitals, who could not be received for want of accommodation; and as a portion of the staff of the Royal Infirmary can undertake the superintendence of the work, it is hoped in this manner to relieve the pressure on the resources of the regular hospitals.

AT a recent meeting of the Edinburgh University Court, besides other business, Dr. A. Wood Smith was recognised as a Lecturer on the Practice of Physic in Glasgow, whose lectures should qualify for graduation in medicine in the University of Edinburgh. On consideration of a report by the Faculty of Medicine, and relative Senatus minute, the following were added to the list of examinations recognised as exempting *pro tanto* from the examinations preliminary to entrance on medical study: 1. The London University examination for degrees in science; 2. The Glasgow University examination for senior candidates for honorary certificates, under its local examination scheme; 3. The examination for commissions and appointments in the Civil Service in the United Kingdom; 4. The Otago University preliminary examination; 5. The examination for the certificate of maturity granted by the Russian authorities for admission to the universities.

In a case recently before the Sheriff Court, at Greenock, Dr. A. D. Stewart of Greenock sued the trustees of the Ancient Order of Foresters' Friendly Society for £25 13s., for professional services rendered to members of the society from December 1863 to June 1870. The pursuer was surgeon to the society from 1843 to 1863. On November 15th, 1863, it was resolved that he should cease to be surgeon; but, at a subsequent meeting of the District Arbitration Committee, he was by a majority declared "duly elected surgeon for the Court". The defenders appealed against this resolution; and at a subsequent meeting of the District Committee, on April 2nd, 1870, the appeal was sustained, and the pursuer was found not to have been duly elected surgeon to the society. The Sheriff decided in favour of the defenders, with expenses. It behoves surgeons to Friendly Societies to see that their appointments are secure before giving their time and services to what may prove a thankless body.

#### DEATH OF DR. ROBERT MUNGALL.

WITH regret we announce the death of Dr. Robert Mungall of Cowdenheath. He had been doing his work as usual until Tuesday, when he was taken ill and died somewhat suddenly on Saturday last. Dr. Mungall was well known throughout the counties of Fife and Kinross, not only owing to his professional skill, but also to the prominent part he took in all public matters, and to his geniality and benevolence of character. In his own district, he was connected with every public board and trust, and his attention was largely devoted to the promotion of educational and sanitary reform.

#### ARBRATH WATER-SUPPLY.

It is proposed to obtain a fresh supply of water for the town of Arbroath from the Crombie reservoir, about seven miles distant from the town, either by purchasing the works which belong to the Dundee Water Commissioners but are not now required for the supply of Dundee, or by paying for water at a fixed rate. This action is being taken in consequence of the urgent representations of the Board of Supervision as to the need of a further supply.

#### TESTIMONIAL TO DR. JOHN BROWN AND DR. A. PEDDIE, EDINBURGH.

ON the 19th ultimo, a deputation from the Foreign Mission Board of the United Presbyterian Church waited on Dr. Brown and Dr. Peddie, at their respective residences, and presented each of them with a piece of silver plate, the gift of a few friends, "in recognition", as stated in the inscription on each article, "of inestimable services gratuitously rendered, for more than a quarter of a century, in testing and conserving the health of their missionaries, and thus rendering his beneficent profession the handmaid of saving health among all nations". The testimonial consisted in each case of a solid silver centre piece, of tripod shape, with top supported by three fluted Corinthian columns, and on the base a standing figure of Esculapius, specially modelled from a terra-cotta in the British Museum.

#### THE SEWAGE OF GLASGOW.

THE Glasgow Town Council and Board of Police have received a report from a deputation appointed by them to inquire into the methods of disposing of sewage adopted in various towns of England. After detailing the methods in use in the places visited, the deputation make the following recommendations, which have at all events the merit of being thorough and sweeping:

"1. That the system of having water-closets for public works, factories, jails, workhouses, infirmaries, and railway stations should be forbidden, so as to reduce the quantity of water-closet sewage now turned into the river. Water-closets in small houses should also be discouraged. 2. That the ordinary privies and ashpits be altered to the tub and pail system, to be cleansed daily, as it has been carried out in Manchester and other important English cities and towns, and that special accommodation be provided for children. 3. That all drains, soil and waste-pipes, and all apparatus connected with water-closets, sinks, and baths, and their connections, be executed under public super-

vision. 4. That a complete system of ventilation of the common sewers throughout their entire length be immediately adopted. 5. That a system of ventilation of the house-drains and soil-pipes, independent of that of the common-sewers, be immediately adopted and enforced throughout the city. 6. That the use, for dietetic purposes, of water from cisterns supplying water-closets should be absolutely forbidden. In the event of its being found necessary to purify the river, 7. That the whole drainage of the city be taken into main intercepting sewers, and conducted to a suitable point, and after being rendered clear by precipitation and filtration, passed into the Clyde. 8. That the sludge obtained in the precipitation process be got rid of in the cheapest possible manner. A part of it might be utilised in making up waste-land, and a certain quantity might be taken away by farmers, but the greater part would probably require to be disposed of in the same manner as the dredgings of the river."

The deputation add:

"It will thus be seen that we entirely discard the idea of utilisation of the sewage itself, or the precipitate obtained by the action of lime or other chemical agents. The sludge obtained by any of the patented processes is dried at such cost, and its value when dry is so trifling, that all hopes of disposing of it for manurial purposes—at a price that would be remunerative—are entirely illusory. In conclusion, we have to remark that, while we consider the purification of the Clyde an important and necessary work, we are of opinion that, for the health of the city, the recommendations we have made upon the other details of the sewage question are of much greater consequence, and we trust that these will be carried out without unnecessary delay."

#### DEATH OF MR. G. P. CHALMERS.

CONSIDERABLE and painful excitement has been caused in Edinburgh by the death by violence of Mr. G. Paul Chalmers, R.S.A., a well known and most rising artist. On the evening of Friday 15th instant, Mr. Chalmers was present at the annual dinner of the Royal Scottish Academy, and went afterwards to the Artists' Club, which he left soon after one o'clock A.M. Shortly after two, he was found lying in a pool of blood in an area in South Charlotte Street, with a badly fractured skull. Mr. Chalmers was taken by the police to the Infirmary, where he died a few days afterwards. He only regained consciousness for a short time, and is understood to have stated that he had been kicked. His watch, purse, and hat were missing. Everything appeared to point to a violent and brutal assault, but, strange to tell, the police took no steps to investigate the matter, and made no inquiries from the medical men in charge of the case, until four days had elapsed from the occurrence of the outrage. A *post mortem* examination was made by Dr. Littlejohn, Dr. J. Duncan, and Mr. Chiene, but the result has not been made public.

## IRELAND.

A CASE of small-pox was admitted into the Limerick Union last week.

AN outbreak of typhus fever has taken place at Ballynagh, a village in the County Cavan; and during the past few days, sixteen cases of the disease have been admitted into the Workhouse Hospital.

THE Local Government Board have approved of an addition of £10 yearly to the salary of the medical officer of the Mullingar Dispensary District.

DR. DAVID HADDEN died at Skibbereen on the 17th ult., aged 60. The deceased was a graduate in medicine of the University of Glasgow, and held the post of medical officer to the Skibbereen Dispensary District.

AT a meeting held on the 14th ult., to elect a medical officer for Castleblaney Dispensary District, Dr. John P. Clarke was appointed. There were three candidates for the post, the emoluments of which are £125 *per annum*, exclusive of salary as sanitary officer and the registration and vaccination fees.

At a recent meeting of the Galway Guardians, Dr. Brodie called the attention of the Board to an irregularity in connection with the Moycullen Dispensary, viz., that the medical officer was in the habit of dispensing medicines to persons coming to the dispensary, and afterwards providing themselves with tickets. It appears that the relieving officer was frequently absent, and that there was no other person to give tickets in the district. The matter will be reported to the Local Government Board, but it appears to us that the fault lies with the relieving officer and not with the medical officer.

#### SANITARY CONDITION OF CARNEY.

A COMMUNICATION from the Local Government Board was received at a recent meeting of the Sligo Board of Guardians, drawing their attention to the defective drainage of this village. The Board pointed out that the guardians were deputed by statute to keep their district in a proper sanitary condition, and that if the public health became affected from the fact that the sanitary authority had neglected to carry out the necessary works for the effectual drainage and water-supply of their district, serious responsibility would be incurred by such neglect.

#### PARSONSTOWN UNION.

At a meeting of the Board of Guardians of this Union held last week, the recent visit of Major Trench, one of the commissioners appointed to inquire into the advisability of amalgamating workhouses, was brought before the guardians. That gentleman was struck with the inconveniently crowded state of the hospital, and found many old people in it who, although bedridden, were not actually under medical treatment, and who, he thought, could be placed in one of the unused rooms in the house. Also, instead of there being too much space for the present number of inmates, there was too little. Under these circumstances, he did not see that they could provide separate accommodation for harmless lunatics and idiots, but suggested that arrangements could eventually be made for their accommodation in Portumna Workhouse. Dr. Woods endorsed Major Trench's statement in reference to the overcrowded condition of the hospital, and had often tried to remedy it without effect. It was ultimately decided to make one of the unoccupied rooms a "bedridden ward", and a report on the subject will be made to the Board.

#### GALWAY WORKHOUSE.

DR. BRODIE, Local Government Inspector, in his late periodical report of this union, remarks that he inspected the house on the 9th ult., and discovered several irregularities in its internal management. In the dormitories occupied by the male infirm classes, Dr. Brodie found the floors soiled and discoloured from urinal discharges; and in one instance, two men occupied the same bed, although there was sufficient space for additional beds; and the master did not appear to visit the ward as often as he should do. The female infirm ward was clean and orderly, but one of its occupants was in a dying state, which requires explanation, as it is obvious that such a case should have been previously removed to hospital, where the patient could have been more carefully and properly cared for.

#### A NOVEL ACTION.

THE guardians of the Limerick Union were last week defendants in an action brought against them by a party of the name of Brennan, whose son had been under treatment in the fever hospital attached to the union, and whilst suffering from fever got out of bed, and falling into a yard was killed. The plaintiff alleged that it was the duty of the guardians who had charge of the hospital to provide sufficient attendants for looking after the patients admitted, and by neglecting their duty they were responsible for his death. Judge Fitzgerald, in pronouncing judgment, stated that the action was not maintainable, for otherwise an action would lie at the suit of every pauper for every real or fancied grievance; for example, for having been supplied with insufficient food, or even for defective sanitary regulations. The

ground of action was a peculiar one, and nothing similar has ever been instituted against the poor-law guardians in Ireland during the forty years the poor-laws have been in operation.

#### WATER-SUPPLY OF WATERFORD.

AN inquiry is proceeding at Waterford for the purpose of considering any objections that may be made to an additional loan of £15,000 to the Waterford Waterworks Committee from the Board of Works, for the completion of the proposed waterworks for this town. The sum of £50,000 has already been expended, and several ratepayers protest against any further outlay, as they consider that the funds already obtained have been mismanaged.

#### WEXFORD WORKHOUSE: TREATMENT OF A PAUPER LUNATIC.

ON the 23rd ult., at the weekly meeting of the guardians, attention was drawn to a report of the visitors, which stated that in one of the female cells they found a lunatic in a most filthy condition. It seems that the infirmarian nuns, who are the paid nurses, neglected their duty of looking after this pauper lunatic; and the matron, on being brought before the Board, acknowledged that she had not entered that particular cell for the past three weeks, being otherwise engaged, and having confidence in the nurses. After some discussion, the guardians ordered that for the future the matron should inspect all the departments of the hospital daily, and be cautious in not permitting the repetition of a similar occurrence.

#### EPIDEMIC OF SMALL-POX IN DUBLIN.

THE epidemic continues steadily to increase. On one day last week, there were seven cases of the disease admitted into Cork Street Fever Hospital; the total number of small-pox patients in the hospital amounting to forty-three. From the Registrar-General's returns, it appears that the death-rate in Dublin for the past week was 3.4.2, against 29.2, the average rate for the past ten weeks. The zymotic death-rate was 5.1, as compared with 3.9, the zymotic rate for twenty large English towns. During the ten months the epidemic may be said to have already lasted, there have been 108 cases under treatment in the Cork Street Hospital; 88 of these had been previously vaccinated and 20 unvaccinated. Out of the 88 vaccinated cases, only 5 were fatal; while 12 of the 20 unvaccinated ones terminated fatally.

#### SCIENTIFIC LECTURES.

THE fourth lecture of this year's course of scientific lectures in the King and Queen's College of Physicians was delivered on Monday last by Dr. Purser, being his second lecture on "Researches in the Anatomy and Physiology of the Spinal Cord". The principal facts which are known as to the functions of the different tracts of white fibres in the cord were stated. The difficulties and uncertainties which beset experimental investigation were pointed out. The results of the more important researches were detailed, particular notice being given to those recently carried on at Leipzig, and being better conceived and more perfectly executed than the experiments of earlier physiologists. The hyperæsthesia which follows certain limited lesions of the spinal cord was stated to be probably due to destruction of inhibitory fibres. The knowledge to be derived from the facts of human pathology was then considered. It was shown that as yet even the best defined diseases, such as posterior or lateral fasciculated sclerosis, were able to throw very little light on the functions of the different parts of the medullary cortex. In conclusion, an attempt was made, from a consideration of all circumstances, to trace the course of sensitive and motor impressions through the cord. It was shown that, while we possessed a fair amount of knowledge as to the paths of motor impulses, many facts existed which made sensitive conduction still quite inexplicable. The next lecture of the series will be delivered on Monday next by Dr. Grimshaw, on "The Present State of our Knowledge of the Intimate Pathology of Contagion, and its Relation to the Prevention and Treatment of Zymotic Diseases".

## THE RELATION OF MEDICAL WOMEN TO THE BRITISH MEDICAL ASSOCIATION.

It is, we believe, proposed to call an early special general meeting of the members of the British Medical Association, to consider the propriety of taking measures to carry into legal effect the opinion of the members taken by vote, that women shall not be elected members of the Association; and also to consider what steps, if any, shall be taken in respect to the two medical women who had been elected members of the Association prior to that vote.

## THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At a meeting of the Fellows held on February 22nd, the chief subject of discussion was the question of which notice had been given by Dr. Elam; viz., "What are the existing relations of the College to the question of the admission of women to the practice of medicine?" It was stated that the College had been informed by counsel that it could not, under its charter, grant its licence to women, or admit them to examination; but that an Act of Parliament had recently been passed (extending the powers, but not rendering compulsory the exercise of such powers) to the granting of any qualification for registration granted by the College to all persons without distinction of sex. It was then resolved:

"That the President summon a meeting as soon as may be convenient to consider whether, under any circumstances, the Royal College of Physicians of London is prepared to grant its licence to practise physic to women."

## REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

THE report of the medical officer of the Local Government Board appears for the first time as a "supplement" to the annual report of the Board, and the volume just issued deals with certain special work done or commenced during 1876. During the first five months of the year, Mr. Simon directed the work of the medical department of the Board, and, during the remainder, it was under the guidance of his successor Dr. Seaton. The actual report by the medical officer is brief, and, after referring to the former reports which had been issued by Mr. Simon since 1859, and which have had so large an effect in shaping professional and public opinion in sanitary matters both in England and abroad, it proceeds to draw attention to the matters dealt with in the appendix which makes up the greater part of the Blue Book.

Amongst the first of the papers published are three special reports by Mr. Netten Radcliffe on Hospital Hygiene, the institutions dealt with being the Radcliffe Infirmary at Oxford, the Norfolk and Norwich Hospital, and the Royal Infirmary at Manchester. When the report on the Radcliffe Infirmary was issued, we discussed it at some length; and it will suffice on the present occasion to point out that Mr. Radcliffe's inspection of the institution was called for owing to the somewhat extensive diffusion of erysipelas within its walls, and that this diffusion appeared to be the result of causes so obvious, that they should never have been allowed to exist. Amongst these we would note that no sufficient isolation of erysipelas cases was attempted, and hence contagion was perpetuated and an infected condition of certain wards was maintained; that, owing to a previous freedom from highly infectious erysipelas in the hospital, such precautions in the matter of cleansing and disinfecting as should always be adopted by surgical staffs when dealing with this disease were allowed to fall into abeyance; that the nurses, both by means of their dresses, which were made of absorbent materials, and in other ways, became carriers of infection from one part of the building to another; and that the position of the laundry as regards the wards, and certain defects in the system of drainage, were calculated to favour the spread of traumatic infection. It is interesting to note that, very shortly after this report was issued, and when a large number of accidents were suddenly admitted into the Infirmary, the patients were remarkably exempt from erysipelas. This immunity, however, followed on the adoption of some of the principal remedial measures which had been urged by Mr. Radcliffe. Erysipelas cases had been isolated, and their linen was separately washed; overcrowding of surgical cases was studiously avoided; proper dresses for the nurses had been provided; sponges were all but

replaced by carbolised tow, which was destroyed after use; and other minor defects had been dealt with.

In the Norfolk and Norwich Hospital, there had been an increasing tendency to fatal pyæmia and of fatal erysipelas amongst surgical cases, and, under these circumstances, the advice of the medical department of the Local Government Board was asked. In this instance, the supervision of pyæmia in the wards appears to have followed on undue overcrowding of cases requiring operative interference: a condition calculated to give rise to an "unmanageable intensity of traumatic atmosphere"; and this state of affairs was associated with defective ward arrangements and management, with insufficient ward-ventilation and sanitary arrangements such as are calculated to render the air breathed by the patients impure, and with an absence of any proper medico-sanitary supervision.

In the case of the Royal Infirmary at Manchester, advice had been specially sought mainly with a view of determining whether the existing building could or could not be made suitable to the present requirements. In this instance, the general plan and construction of the hospital were found to be faulty; the drainage and numerous other sanitary arrangements were extremely defective; the building was overpacked, surgical overcrowding being very marked; and recurring outbreaks of traumatic erysipelas had taken place.

These reports, which we have only been able to glance at in a cursory manner, deserve the serious consideration of all who are concerned in hospital administration. In a large number of hospitals, no scientific records are kept which will enable a proper judgment to be formed as to the hygienic condition of the institutions; and one of the points specially urged by Mr. Radcliffe is that, in every hospital, some person should be appointed whose duty it should be to have a direct and special responsibility for its daily sanitary supervision. Ill-kept hospitals are certain, sooner or later, to favour the spread of such diseases as gangrene, phagedæna, pyæmia, and erysipelas; unless such ventilation be secured as shall leave no corner unsearched by its currents, wounds are liable to go on badly; and, where water-closets, baths, and the ward-offices open either directly into the wards or into the main body of the building, the purity of atmosphere necessary to keep traumatic infections in check cannot be expected. And yet such conditions as these, coupled with the absence of proper means for immediately isolating such affections, are, we fear, only too common in the present day, and they constitute a cause for anxiety as to the results of operations which no amount of surgical skill can overcome. Their remedy must to a great extent be in the hands of the medical staffs, with whom the responsibility of such results as we have enumerated must to a great extent lie.

Another contribution to the volume is a report, which is the result of a lengthened inquiry by Dr. Ballard as to Effluvium-Nuisances arising in connection with various manufacturing and other branches of industry. As yet only one division of this report has been completed; namely, that relating to the keeping and slaughtering of animals, and to those industries in which substances of animal origin are dealt with; but it is to be followed by other divisions in which nuisances arising from industries in which vegetable, mineral, and mixed substances are considered. The principal object of this inquiry has been to ascertain how far effluvium-nuisances arising from various manufactures are injurious to health, and to what extent they may be prevented. The result so far is highly satisfactory; for the tendency of the evidence obtained is to show nearly all, if not all, the trades now causing offence from the diffusion of effluvia may be so carried on as not to cause offence at all, or only offence of such a trifling nature as may well be tolerated by persons who live in communities. The extensive nature of Dr. Ballard's investigations may be guessed at when it is stated that, in dealing with the question of the manufacture of artificial manures alone, more than eighty places of business were inspected in various parts of the kingdom, and that as many as twenty-eight different industries are discussed in the present volume. These include a large number of the offensive trades now commonly carried on in towns, such as those of the fellmonger, the tanner, the candle-maker, the boiler of bones, and the size manufacturer. The exact nature of the various trades is fully described, and many of the unnecessary evils associated with them are discussed. The report, which is copiously illustrated, is calculated to be of great general utility, and in its results it may possibly vie with that issued a few years ago by the medical department on the means of preventing excrement nuisances in towns and villages.

The concluding report is a memorandum by Mr. Netten Radcliffe on the Progress of Levantine Plague from 1875 to 1877. The outbreak described appears to have commenced in 1873 amongst the Arabs inhabiting some of the marshes to the east of the Euphrates, and to have recurred in the spring of 1874, when it caused about four thousand deaths. It subsided during the summer months, but reappeared in the

winter of 1874-75, and became much more widely spread. On the setting in of the hot season in 1875, it seemingly ceased, only, however, to become again developed; and it is the course of the disease from November 1875 that is mainly dealt with in the present memorandum. The neighbourhoods of Bagdad and of Hillah seem principally to have suffered, the greatest activity of the disease being from the end of February until April, when it commenced to decline, the epidemic ceasing about July. The ravages of the disease were, however, great, and the minimum mortality during the outbreak of 1875-76 is estimated at twenty thousand. With the recurrence of colder weather in October the epidemic again appeared, it having now reached a higher point up the Euphrates Valley. The disease again lasted through the winter, and was still in existence throughout the early part of 1877.

Not till late in the course of this great epidemic were any measures adopted for staying the spread of the disease, and even then those which were attempted were of so vexatious a nature, that they were evaded on all hands.

## ASSOCIATION INTELLIGENCE.

### LANCASHIRE AND CHESHIRE BRANCH.

THE first intermediate meeting of this Branch will be held at the Town Hall, Oldham, on Tuesday, March 5th, at 3.30 P.M.

Dr. W. H. Broadbent (London) has kindly consented to read a paper on the Mechanism of Speech and Thought as illustrated by Pathology.

The following communications have also been promised.

Dr. G. J. Robertson will read the history of a case of Multiple Mammary Tumour.

Dr. Lloyd Roberts will exhibit some specimens of Distorted Pelves.

Dr. Humphries will read a paper on Scarlatinal Nephritis, and show specimens illustrating its pathology.

Dr. Dreschfeld and Dr. Ross will exhibit, by means of the Oxyhydrogen light, Microscopic Sections illustrative of Disease of the Spinal Cord.

Mr. Jones will show a specimen of Necrosis of the Femur following Acute Suppurative Periostitis.

Dr. Leech and Mr. Cullingworth will show cases of Pseudo-hyper-trophic Paralysis.

Members wishing to read papers or to exhibit specimens, are requested to communicate with the Honorary Secretary as soon as possible.

Dinner will be provided at the Angel Hotel at 6 o'clock. Charge, 5s., exclusive of wine. Members intending to dine are requested to send their names to Dr. G. Thomson, Oldham.

D. J. LEECH, M.D., *Honorary Secretary*.

96, Mosley Street, Manchester, February 13th, 1878.

### NORTH WALES BRANCH.

THE intermediate meeting of this Branch will be held at the Owen Glyndwr Hotel, Corwen, Merionethshire, on Friday, March 8th, at 1 P.M.: R. ROBERTS, Esq., Portmadoc, President.

The Honorary Secretary will relate a case (with specimens) of Aneurism of the Ascending Aorta.

Members wishing to read papers or exhibit specimens are requested to communicate at once with the Honorary Secretary.

T. EYTON JONES, M.D., *Honorary Secretary*.

Wrexham, February 18th, 1878.

### BATH AND BRISTOL BRANCH.

THE fourth ordinary meeting of the session will be held at the Museum and Library, at the top of Park Street, Bristol, on Wednesday evening, March 13th, at half-past 7 o'clock; H. MARSHALL, M.D., President.

The following papers are expected.

1. J. G. Swayne, M.D.: Case of Puerperal Convulsions.

2. W. H. Spencer, M.D.: The Use of Salicylic Acid in Combination with Opium and Aconite.

3. R. S. Smith, M.D.: Cases illustrating the Treatment of Pleuritic Effusion.

4. A. E. A. Lawrence, M.D.: On certain Forms of Non-Puerperal Uterine Hæmorrhage.

A train leaves Bath at 6.35 P.M., and returns from Bristol at 10.15 P.M., Great Western Railway.

E. C. BOARD, *Honorary Secretary*.

7, Caledonia Place, Clifton, March 1st, 1878.

### THAMES VALLEY BRANCH.

THE next general meeting will be held on March 14th, at the Griffin Hotel, King-ton, at 5 o'clock.

Papers will be read by Dr. Price Jones and Mr. George Farr White, F.R.C.S.

There will be a dinner at the above hotel at 7 o'clock. Charge, 7s. 6d., exclusive of wine.

Those members who intend to be present are requested to write to the Honorary Secretary.

F. P. ATKINSON, M.D., *Honorary Secretary*.

Kingston-on-Thames, February 28th, 1878.

### YORKSHIRE BRANCH.

THE spring meeting of this Branch will be held at the Infirmary, Rotherham, on Wednesday, March 27th, at 3 P.M.

Members wishing to read papers or bring forward cases are requested at once to communicate with the Secretary.

After the meeting, the members will dine together at the Ship Hotel at 5 P.M. Tickets (exclusive of wine) 6s. 6d. each.

W. PROCTER, M.D., *Honorary Secretary*.

York, February 26th, 1878.

### SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT MEETINGS.

THE next meeting will be held at the Crystal Palace Hotel, Upper Norwood, on Thursday, March 14th, at 4 P.M.: R. M. MILLER, M.D., in the Chair.

The following papers are promised.

1. Mr. Golding Bird: The Treatment of Scrofulous Glands by the Electrolytic Caustery.

2. Dr. Poole: On the Non-Alcoholic Treatment of *Post Partum* Hæmorrhage.

3. Mr. Sidney Turner: A Case of Abdominal Tumour.

4. Mr. Sidney Turner: A Case of Opium Poisoning.

Dinner will be laid at 6 P.M. Charge, 6s. a head, exclusive of wine.

JOHN H. GALTON, M.D. Lond., *Honorary Secretary*.

Woodside, Anerley Road, S.E., February 26th, 1878.

### SOUTH-EASTERN BRANCH: WEST SURREY DISTRICT.

THE next meeting of the above District will take place at the Surrey County Hospital, Guildford, on March 21st, at 3.45 P.M.

Members wishing to read papers are requested to communicate with the Secretary at once.

There will be a dinner at the White Lion Hotel, at 6 P.M. Charge, 7s., exclusive of wine.

A. ARTHUR NATTER, *Honorary Secretary*.

Cranleigh, February 26th, 1878.

## CORRESPONDENCE.

### SUBCUTANEOUS INJECTION OF ATROPIA.

SIR,—In the interests of humanity, and in reference to "a case of opium-poisoning successfully treated by atropia" reported in the BRITISH MEDICAL JOURNAL of February 23rd, I write to say that *one grain of pure sulphate of atropia* injected under the skin will, whether opium has been previously taken or not, usually prove a fatal dose.—I beg leave to remain faithfully yours,

JOHN HARLEY.

Brook Street, Grosvenor Square, W., February 22nd, 1878.

### THE MEDICAL BENEVOLENT FUND.

SIR,—I would venture to suggest that each honorary secretary should follow the example of the energetic secretary of the South-Eastern District, and, when sending the usual application for the annual subscription, should offer to take charge of a subscription for the Medical Benevolent Fund. It might be the means of gaining additional subscribers, and it would save a great deal of trouble, as one cheque covers all three subscriptions: that for the Association, that for the Branch, and that for the Benevolent Fund.—Yours, etc.,

FRANCIS H. PARSONS.

Mount Pleasant, Hastings, Feb. 20th, 1878.

# THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

SIR,—Dr. Falconer's reply to my letter leaves matters in a position still more unsatisfactory than I had anticipated. His letter is still more unintelligible than the report of the Proceedings of Council, of which I complained as being more likely to mis-inform than inform members of the Association of what really occurred at the meeting of which they pretend to report the proceedings. Let me analyse his letter.

1. Dr. Falconer says: "I am responsible for the delay", etc. I congratulate Dr. Falconer upon the light-heartedness with which he passes over, without a word of explanation or regret, a considerable delay in the publication of proceedings so important to the Association at a critical moment. The formula "accidental circumstances" has, within my brief experience, unfortunately too often been applicable already to omission to perform duties connected with important business of the Association by the central executors of affairs. I will, however, pass by this incident. If Dr. Falconer feel no regret for the unfortunate circumstance that Dr. Wilson Fox's letter appeared in all the medical journals, including our own, before the publication of the Proceedings of the Committee of Council to which it relates, I am sure that the Association in general feels regret.

2. Dr. Falconer states that he is responsible for the imperfect and unintelligible form in which the so-called report has been published, and that in this report he has anxiously followed the practices of his predecessors. I am not old enough to know how far this aspersion upon his predecessors is accurate or not: of his immediate predecessors I believe only one, unhappily, is alive to defend himself against such a charge.

3. With singular inconsistency, however, after announcing his personal responsibility for omitting from the reports the most highly important facts in the Proceedings, Dr. Falconer refers me for any remedy to the next meeting of the Committee of Council; that is to say, he first attempts to shift on the Committee of Council a responsibility which he has just admitted to be purely his own; secondly, by this means he proposes to defer for two months at least the publication to the members of the Association of the vital facts of those proceedings which concern the largest interests of the Association in respect to 1. Membership; 2. Finance and the disposal in a judicious (and I contend in a wasteful and injudicious) manner of large amounts of capital; 3. The privileges of members at the annual general meeting.

I wish, therefore, to point out to Dr. Falconer that his letter does not convey the information which the members of the Association have a right to expect. He has informed them that it lies in his hands to let them know what was the amendment proposed and seconded at the meeting of the Committee of Council, on the subject of the letter of Dr. Fox. What would Dr. Falconer himself think of a report of the proceedings of the House of Commons without a report of any of the amendments proposed? It lies with him also, as he has told us, to give to the members the full and real statement of facts as to what it is proposed in respect to taking the house, as to which the only information yet given is, that £320 *per annum* is to be paid for the rent, and that the premises are to be insured. Were not much more important financial resolutions passed at the same time and on the same subject, including the expenditure of £1,500 on leasehold premises, and the undertaking of a printing business, which information he has kept back from the Association by the method he had adopted in his "selection from the minutes"?

Were not also most important regulations passed at the same meeting affecting the privileges of members at the annual general meetings? Is it not fair to the members of the Association that these facts of the Proceedings should be published at once, in order to afford time to the members to undertake questions so dealt with, and, if they have any suggestions to make, to allow them to make such suggestions sufficiently early for consideration at the next meeting of the Committee of Council?

In respect to the Proceedings of the Habitual Drunkards Committee, will Dr. Falconer explain how the rule operates which, in this case, prohibits the publication of all except the amendment, while, in the case of Dr. Fox's letter, it expressly excluded the amendment?

I earnestly beg Dr. Falconer to weigh well the grave importance of not persisting in keeping members in ignorance of these important matters at this critical juncture. He admits that the responsibility of dealing with the minutes rests with him; is he sure that Sir Charles Hastings, Dr. Sibson, or Mr. Southam, whose *names* he invokes, would have insisted on a policy of secrecy on such an occasion? At any rate, I would ask him to remember that the responsibility is his to state

definitely to members whether he will respond to the appeal and publish forthwith an intelligible report of the Proceedings of the Committee of Council, including those parts to which I have referred.

I have the honour to remain, etc.,  
W. C. GRIGG, M.D., Honorary Secretary to the  
Metropolitan Counties Branch.

6, Curzon Street, Mayfair, February 25th, 1878.

## THE LATE DR. D. DONOVAN.

SIR,—May I ask for your kind assistance in promoting the memorial to the Prime Minister on behalf of the family of the late Dr. Donovan? I need not enumerate the claims of Dr. Donovan on the country, as these are set forth in the accompanying memorial, clearly, but without exaggeration.—Faithfully yours,  
A. HUDSON, M.D.

Loweville, Dublin, February 1878.

The following is the memorial referred to in Dr. Hudson's letter.

*To the Right Honourable the Earl of Beaconsfield, First Lord of the Treasury.*

THE petition of the undersigned humbly sheweth—

That Daniel Donovan, M.D., Edinburgh University, 1828, L.R.C.S.E., L.M.E. (Dub. and Edin.), late Medical Officer, Skibbereen Workhouse and Dispensary, died on the 30th September, 1877, aged 69, at Skibbereen, in the county of Cork, Ireland, leaving him surviving his widow, Henrietta Donovan, and, amongst other issue, four unmarried daughters, Helena, Frances, Mary, and Margaret, two of whom are in delicate health.

That, for eight years before his death, the said Daniel Donovan suffered from a lingering disease, by which he was entirely incapacitated from any professional work whatever, and confined to his room.

That, as a consequence of the said protracted illness, and of the failure of the Albert Life Insurance Company when he was broken down in health (in which Company his life was largely insured for his wife and daughters), Dr. Donovan was entirely unable to make any provision for his widow and unmarried daughters as aforesaid.

That, during the said illness, his principal means of support was a small pension from the Skibbereen Board of Guardians, voted to him on his retirement from the position of their medical officer, which pension ceased on his death.

That one of the sons of the said Dr. Daniel Donovan was Dr. Jeremiah Donovan, late of the Royal Navy, who, after active and zealous services in his capacity as naval surgeon on the West Coast of Africa, died soon after his return therefrom of the effects of a disease, the seeds of which were laid by his service in the unhealthy climate of the West Coast; and that, owing to his death, his mother and sisters were deprived of one who contributed to their support and welfare.

That, during his lifetime, the said Daniel Donovan was enabled, at a great crisis in the history of his country, to render extraordinary services to humanity; and that his original medical researches and observations have been recognised by the most competent authorities as among the most valuable contributions to medical science in his time.

That the town of Skibbereen and the district around it notoriously suffered more severely from the great famine of 1846-7 than any other part of Ireland.

That, at the time of the said terrible calamity, Dr. Donovan was the Poor-law Medical Officer for the town of Skibbereen.

That Dr. Donovan made the most superhuman exertions to grapple with the famine; that he spent day and night succouring the sick and feeding the hungry; that he was the centre and organiser of all efforts to relieve the famishing west of Ireland; that his letters to the *Times* and other English journals, by making known the extent of the famine, secured large pecuniary aid for the suffering poor; and that he thus rescued thousands from disease and death.

That, moreover, the said Dr. Donovan recorded his medical experiences of this period in the columns of the *Dublin Medical Press*; and that the papers thus contributed by him have ever since been regarded by medical writers as the great original authority on the symptoms of starvation as they occur in the human subject.

That Dr. Donovan's position, as the great original authority on this subject, is fully recognised by Dr. Taylor in his celebrated work on *Medical Jurisprudence*, by Dr. Casper, the principal German writer on the subject, and by all recent writers on forensic medicine, both English and foreign.

That, during the recent great famine in Madras, the observations of Dr. Donovan were most valuable to the medical men employed in succouring the starving people, as enabling them to diagnose between the symptoms of starvation and disease, first clearly distinguished by Dr. Donovan.

That no reward whatever was conferred, nor did profit of any kind accrue to the said Dr. Donovan, from the said researches; and that his position as a medical man in a small country town, with a family of eleven children, prevented him from making due provision for his family, save by the insurance lost as aforesaid.

That, having regard to the said services, your petitioners humbly pray your lordship to advise Her Majesty, in consideration of the great services to humanity and science by the said Dr. Donovan, to grant his widow and unmarried daughters aforesaid a pension from the Civil List; and your petitioners will, as in duty bound, ever pray.

## THE TEACHING OF NATURAL SCIENCE IN MEDICAL SCHOOLS.

SIR,—Some nine years ago, the General Medical Council addressed to the various teachers in our schools of medicine a circular letter containing a number of questions on the subject of professional education, on which they invited an expression of opinion. In my reply, I ventured to say:—"I have, with others, often thought that the teaching of these subjects (anatomy and physiology), instead of being distributed amongst our several hospitals, might be much more beneficially carried on at some one or two central colleges. I believe that such a plan would afford advantages, resulting from a concentration of force, which would far outweigh any objections to it."

Even then this idea was far from being a new one, and ever since continued observation and reflection have so strengthened the conviction that some such scheme as this ought to be carried out, that at length I am induced to trouble you with this letter.

I think all must admit that the usual mode of teaching anatomy, physiology, chemistry, and botany in our medical schools, is very far from being satisfactory. With the exception of two or three of our largest schools, the classes are too small to afford the least encouragement to any teacher; nor could competent men be induced to lecture on these subjects, were it not that such appointments are considered to be almost necessary stepping-stones to something better in the future. The consequence is, that the lectures aforesaid are made only a means to an end, and such appointments are thankfully resigned upon the earliest opportunity. To fill such an office in this way for a time may, no doubt, be of advantage to the teacher, and go far to advance the more scientific part of his education; but what can be said of it for the student?

If, instead of having the classes on these subjects split up among a number of small schools, the natural sciences were all taught at one place, it is not impossible to foresee that the gain to our students would be immense.

The classes would be so large that the services of the best men could be secured for teaching, and the appointments would be so valuable, that they would be earnestly sought for their own sake. Furthermore, if it were deemed advisable, some or all of the subjects might be so divided that each part could be taught by the man who, of all others, best understood it.

In this way, the hospitals would be relieved of a burden which each year presses more and more upon all; upon some so heavily that the work can hardly be carried through. But, if our medical schools were relieved of having to teach natural science, all their energy might be concentrated upon their own more immediate business of instruction in medicine and surgery.

Beyond these advantages, there would be a great gain in the order of teaching. A student now comes to a hospital fresh from school, and forthwith finds himself face to face with a host of subjects, all of which, some even by name, are painfully strange to him, and each one apparently so complex and difficult that, without any previous introduction, he cannot tell how or where to begin, and, in a conscientious endeavour to do justice to all, he attempts to grapple with subjects which as yet are quite out of his reach, and ought to be left alone until, by the previous study of others, he has been educated up to them. Some previous knowledge at least of anatomy, physiology, and chemistry is necessary to the intelligent study of medicine and surgery.

Of late years, it is true this radical evil has been partially met by a division of the examination at the College of Surgeons into a primary one in anatomy and physiology and a pass one in surgery; so that, as far as the examination is concerned, students may not have the burden of all these subjects upon their minds at once. But, after all, what does this imply? If students, as is usual, work only for their examinations, the study of medicine and surgery at the hospitals becomes limited to a period of less than two years, which is ridiculous. And if, according to the presumption, students are expected to "go

round the wards" during the whole term of their attendance at the hospital, "clinical work" becomes nothing better than a farce. What is a man to learn by thus sauntering through the wards without any previous instruction in medicine and surgery?

Now, if from school he could pass first of all to an institution to study anatomy, physiology, and chemistry, just as other men go to college, he would not only receive the best possible training for his future career, but he would, in course of time, come to the hospital so educated as to be able to enter upon the study of medicine and surgery under fair conditions. He would be able to make the best use of his time, or at least to avoid wasting much of it.

Of course, I would not have the time to be spent in the study of the natural sciences at a central college subtracted from the period of work at a hospital. I wish to avoid all detail now, and to speak only of the plan in general; but at least three years should be spent at a hospital in the study of medicine and surgery after two years' previous work in anatomy, physiology, and chemistry. This would make a total of five years for professional education. Such a time may be, and I for one think it is, too short, but assuredly it is not an hour too long.

I will not lengthen this letter by dwelling upon other advantages which would wait upon this scheme; such, for example, as the way in which it would strengthen the bond between the study of the natural sciences and the practice of medicine and surgery, an union which I am ashamed to say is too often shaken by those who should be amongst the foremost in cementing it more closely. For I would rather let the case rest upon the three points I have endeavoured to indicate.

But I am not sanguine that this plan will in any fashion be carried out, at least for a long time. I know that its advantages are realised by some whose authority on questions of education stands highest; but then I suppose there would be too much difficulty in matters of detail. The scheme, to be in any way efficiently carried out, would involve some individual sacrifice on the part of many, and of these some, by mere passive resistance, could place such obstacles in the way of any change of this kind, that the plan would have no chance of surviving the stage of discussion.

But, whatever the fate in future of any such arrangement may be, I at least am glad of the relief which comes of writing this letter.—I am, sir, your humble servant.

WILLIAM S. SAVORY.

London, February 26th, 1878.

## HOSPITAL FINANCE.

SIR,—I agree with you in thinking that the time is rapidly approaching when some very active reforms will have to be introduced into the management of the large metropolitan hospitals. It is not my purpose to-day to dwell upon the close relations which exist between irresponsible relief and increasing deficiency of funds; for you have already, and with justice, dealt at length with that branch of the subject which relates to the unlimited and ever increasing medical relief afforded almost without restriction to all applicants. Such a condition of affairs must, in a time of depression like the present, undoubtedly increase the deficiency in the accounts of which so many hospital managers at present complain. But, apart from this, I am convinced that the system of management, or rather want of method, which regulates the financial departments of most of the metropolitan hospitals, is based upon unsound principles. So far as any general rule can be said to exist, such rule lays down that it is useless to attempt to obtain annual subscriptions, and so it is best to be thankful for what donations can be obtained by appeals, festivals, and so forth, each year and year by year; and, when these do not suffice, with the interest on invested property, to meet all the expenditure, a sale of stock supplies the deficit. In the provinces, such a system finds no favour; but there, as a rule, annual subscriptions form the financial backbone of each of the medical charities. If this be doubted, I would merely point to the fact that the comparatively recent cottage hospital has proved this beyond dispute; for eighty cottage hospitals, having an aggregate income of £30,000, derive 48 per cent. of it, or £14,500, from annual subscriptions alone. Yet it has been proved by experience that it is not more difficult to obtain annual subscriptions for a London charity than for a country one, providing the same kind of method be employed with steady pertinacity. The economy of procuring annual subscriptions must be manifest to everyone. It does not cost more than 5 per cent. to collect an annual subscription when once it is procured, whereas a donation, each time it is paid, costs a variable sum of from 15 to 25 per cent. at the better managed and larger institutions, and who shall say how much at some others which shall be nameless? What is the reason, then, that an institution with an expenditure of £30,000 a year derives but £2,000 from annual subscriptions, and has to sell out

£38,000 of stock in two years to meet its current expenses? Simply that the question of financing our large hospitals has never yet received the attention which it deserves. Much surprise has been expressed that the London Hospital has been compelled to sell £21,000 of stock in one year. It seems to me that this surprise will be materially modified, when I state that it is a rule at most hospitals to make up the deficiency on general account by a sale of stock year by year. If a good year come, well and good; then some funds are invested; if not, then capital account suffers. To show more clearly how this system works, I will quote two examples.

A has an expenditure of £23,000 a year; B has an expenditure of about £12,000. In one hundred years, A has received for investment the enormous sum of £345,000, of which it has spent £241,700, or an average of nearly £2,500 a year. In the first four decades, the amount derived from annual subscriptions was £2,200 on an average. In the next six decades, the annual subscriptions gradually increased to £6,100; but the expenditure had risen from £5,700 to £18,200; so that the annual subscriptions showed no proportionate increase, although at the outset they were nearly equal to the expenditure, being £2,243 and £2,290 respectively. Recently, a stir was made, and the annual subscriptions reached £8,700; but they have since been allowed to fall to £8,200, which I regret to say is the largest sum derived from this source by any London hospital.

In the case of B, the information is not forthcoming for so long a period; but, in ten years, £20,212 of capital was sold out—an average of £2,021 a year—to meet current expenses. The managers' attention was called to the system a few years ago, and they resolved to put a stop to it and try the plan of annual subscriptions. Steps were taken to raise the subscription-list to something like an adequate sum, and their experience proves that this can be done with success; for in three years they have procured £1,700 in new annual subscriptions: a sum more than double the average subscription list of the previous fifty years; they have also paid off an old debt of considerable extent, and their expenditure for management has been but 9 per cent. Not a single penny of invested capital has been spent since the new plan has been at work (three years), although the work of the institution has much increased. If only the managers of the metropolitan hospitals would try this system, and by publishing each year, in a tabular form, the returns they make to the Council of the Hospital Sunday Fund, would afford each other and the public generally the means of watching the progress these institutions are making, much would be done.

But, in my opinion, what we really want is an annual conference and a working committee of representative managers of our medical charities. There are social congresses, conferences of librarians, head masters of public schools, Poor-law officials; why not of hospital managers? The hospital managers spent, in 1877, no less than £545,000 of public money, and surely a little joint action on their part would tend to promote the public good. I shall be glad to hear that some steps are being taken to form such an association as I propose.—I am, etc.,

HENRY C. BURDETT.

Greenwich, S.E., February 1878.

#### MATERIA MEDICA EXAMINATIONS.

SIR,—Students can hardly have failed to note with satisfaction the resolution passed by the General Medical Council last summer, with reference to the definition and limitation of the areas of examination in certain of the most oppressive subjects. In other words, they are no longer to overload their memories with every fact and detail contained within the wide-reaching limits of chemistry and materia medica; but certain regions are to be mapped out, within which their knowledge is expected to be precise and accurate. Such at least is the theory of the matter, and for its practical solution we must await the decision of the examining boards; but I may venture to suggest that the summer session will soon be here, and that teachers of materia medica may not unreasonably look for some lines to guide them in their forthcoming lectures. Are they, as formerly, to wade through the dreary pages of the *Pharmacopæia*, describing processes and reactions which are as dull as they are profitless? or may they in future confine their attention to points of real importance, and leave out of all consideration much of that wearisome detail which wastes many a precious hour? It is, of course, impossible that this selective power should be wielded according to individual caprice; but I would venture to suggest that some comprehensive scheme might be drawn up, to be submitted to the great medical corporations and modified or adopted by them. Professor Harvey and Dr. Lauder Brunton have already done good service in this direction; and the further development of the subject might be taken up by the

materia medica lecturers in conclave, or by the Medical Teachers' Association, if that body still exist.

Will you allow me, with such brevity as the importance of your space demands, to make one or two suggestions? In the first place, it must be understood that the student should possess a good working knowledge of the physiological actions and therapeutical applications of the drugs included within the horizon of examination, but that the pruning-knife must be freely used, and many substances struck out of the list on which he is now expected to bestow some portion of his sorely taxed memory; and on this point Professor Harvey's tables may be well taken as a basis of arrangement.

Secondly, much abridgment must be made in the present wide field of pharmacy.

Were I enabled to follow out my own views, I should banish all such detail from our lecture-rooms and examination-tables; but we are as yet hardly ripe for this, and can only expect to obtain some relaxation of the present rigid limits. Therefore, I would suggest that, of the larger groups of inorganic substances, the precise mode of manufacture of the compound from which the others are prepared, with, perhaps, one prominent member of the family, should alone be learned. Thus the potash salts are derived from the carbonate, and this may be retained as an examination subject, whilst the iodide may also be included, on account of its importance. But, of all the other varied preparations, the general actions and dose of the bicarbonate, acetate, acid tartrate, nitrate, and bromide should be the full extent of the knowledge to be expected.

Of the iron salts, the formation of the sulphate and perchloride, as illustrating a broad chemical distinction, should be learned, and the doses of the other preparations given in large capitals by Harvey and Brunton must also be known; whilst mercury may fairly be restricted to the chloride and perchloride, in addition to the various pills, ointments, powders, and plasters derived from the crude drug itself.

Your space does not enable me to go further into detail; but the same principle may be applied to all the inorganic substances, and a variety of excisions may also be made among the organic articles of the *Pharmacopæia*.

Thirdly, I would suggest that the student should no longer be expected to know anything about the adulteration of drugs. This is seldom of clinical interest, and, as it concerns almost entirely our wholesale druggists, medical men may well be excused if they wish to protect their brains from the intrusion of useless lumber.

Fourthly, botanical characters should be remembered only in connection with the more common poisonous plants, as belladonna, conium, etc., where such knowledge may often be of real medico-legal importance.

Fifthly, let the student, as a mere matter of observant training, make himself thoroughly acquainted with the physical characters of the various drugs, without being expected to furnish in writing any of the elaborate descriptive detail laid down in the *Pharmacopæia*. Although useless in itself, I have found, as a rule, that my students do not chafe against this as against the equally useless intricacies of pharmacy, but speedily acquire a rapid power of recognition of a very satisfactory nature; and I would ascribe this toleration to the fact that specimens of the leading drugs are freely displayed in drawers, where members of the class can at all times inspect and handle them for themselves.

Sixthly, and to conclude, concerning the alkaloids; this has always been rather a stumbling-block in the student's way, as the six in which he is most usually examined, are prepared by methods so far varying from one another as to be brought with difficulty, if at all, under any systematic classification. I would, therefore, suggest that morphia, as a representative of the others, should be studied thoroughly, and that some idea might be obtained as to how the others differ in preparation. Thus, dividing the process into three stages, we have: 1. Extraction by spirit, by percolation and exhaustion in aconitia, strychnia, and atropia; exhaustion and evaporation with water in morphia and veratrina; by hydrochloric acid in quinia; 2. Purification by successive solutions in water or spirit and evaporation; colouring matter removed by precipitation or animal charcoal; grosser impurities, such as the meconic and lactic acids in opium, by combination with chloride of calcium, resin, and igasuric acid separated from strychnia by acetate of lead, brucia removed by washing with spirit and water; from atropia, colouring matter and organic acid are removed by lime; 3. Precipitation and separation by ammonia in morphia, aconitia, strychnia, and veratrina; by solution of soda in quinia; by carbonate of potash and chloroform in atropia.

I should have liked to go much more closely into detail in the consideration of this important subject, but wish rather to ensure its free ventilation and discussion than to obtrude my own views. So long as the teaching of materia medica is compelled to continue on its present

footing, so long do we perpetuate the vices of grinding in their worst form; and by these I do not mean the orderly and systematic digestion of crude masses of reading, which is often beneficially provided by professional coaches, but the wholesale cramming into the memory by the student himself of facts and details from one or other of the abbreviated manuals. No amount of lecturing power can galvanise any interest into pharmaceutical detail, and the student most naturally postpone all attempt at acquiring any familiarity with so distasteful a subject until the coming event of the examination begins to cast its grim shadow before; and no sooner does he become a qualified man than he restores the elasticity of his brain by casting much of its tightly packed cargo overboard. Far be it from me, sir, to advocate any reduction of the due amount of knowledge possessed by medical men; but there comes a point when mental training, as conducted by practically useless things, must cease, and all the time at command be devoted to the mastering of the actual facts and details of future professional life. The philosophical consideration of these affords intellectual problems of the highest variety and importance, and we must take care that we do not place needless obstacles in their way.—I am, sir, your obedient servant,

ROBERT FARQUHARSON.

Brook Street, February 1878.

### PHYSICIANS, PRACTITIONERS, AND FEES.

SIR,—Your correspondents on the subject of fees seem to think that pure physicians admit of being divided into popular leaders, who make their income mainly by consulting with the family doctors of the wealthy, and needy failures, who have degenerated into general practitioners. No account has been taken of a class, not small in numbers, to which I belong, and which necessarily disturbs the proper constitutions which your correspondents draw up for the profession. Though my position in the profession is very good, yet circumstances have prevented my getting a footing in the good graces of the upper classes, and I have few patients indeed of social rank equal to my own. The names in my case-book are those of farmers, tradesmen, artists, literary hacks, the inferior clergy, clerks, publicans, artisans, and even domestic servants. If they confess to having a family doctor, I always write him a note of my diagnosis and proposed line of treatment. But I have reason to believe the majority come to me for the very purpose of avoiding the employment of a family doctor, and, on economical grounds, are willing to pay two guineas the first visit and a guinea for subsequent visits, and to carry out any variations required in the treatment for themselves when put into possession of its *rationale*. The only persons who demur to a full physician's fee are the vulgar rich, who have apparently come to an unfashionable physician in the hope of getting advice cheap. For us to give up this line of practice and refuse to see patients without a family attendant, is simply to shelve ourselves altogether and starve; for it is evident there is not enough strict old-fashioned consulting practice to feed one-twentieth of that formidable list which I have just received from the Royal College in Pall Mall. Moreover, the effort of the Charity Organisation Society to purge the out-patient department at hospitals augments considerably our *clientèle*, and the establishment of private pay hospitals will enable us to add acute cases to our list. But I cannot conceal from myself that we are diminishing the aggregate income derived by the profession from the public, nor do I see how that result can be avoided.—I am, sir, yours faithfully,

February 22nd, 1878.

F.R.C.P.

SIR,—As it is probable that the favourable notice of my paper (January 19th, 1878) in your leading article (February 9th) on "Physicians, Practitioners, and Fees" will call forth some further remarks, allow me to anticipate certain adverse criticisms, which would otherwise assuredly be given. I will direct attention to two particulars only which are most liable to be misunderstood, and which, when misunderstood, are valid grounds of objection.

First, the plan proposed is not that which "obtains in many parts of the Continent". It is like it, but there is a very important, an essential, difference between them. The Continental plan, sometimes called "the Chinese plan", is simply "payment *per annum* for medical attendance", instead of "payment *per visit*". Mine is "payment *per annum*", it is true, but the annual sum covers only *ordinary* service.

(A simple and easily applicable rule is given for defining what service is "ordinary" and what is not). Secondly, the Continental plan says nothing about "fees"; my plan makes express provision for them under the head of *extraordinary* service (which also is defined in a simple common-sense way). In other words, the Continental plan is primarily commercial; it is a bargain, a contract "to include everything". Mine is primarily professional; the commercial view is not ignored, but it is kept in its proper place, strictly subordinate to the professional. If my plan were nothing more than the "Chinese" system, it would not be worth the paper on which it is written; but, as a proposal in strict accord with the most advanced views of medical science, calculated both to further medical science and to make it popular, I submit it with confidence to the members of the British Medical Association, and through them to the public.

The other point liable to misapprehension is that, in applying the principle of co-operation to my plan, it seems to be "open to the objection that medical men would be called upon to do for the public what the public ought to do for themselves". If this be so, I would be the first to denounce it. I would not ask "the profession to part with a third of its fees", nor a hundredth part of its fees, "for charitable purposes". I hate expediency in every form, and none the less when it puts on the garb of charity. I will neither prostitute virtue nor cheat the profession. I ask for a third, not of the doctor's fees, but of a sum contributed for a certain definite purpose, and I ask for it simply on the supposition that this is the just proportion. The work to be done can only be done by making an united effort. As much as possible of the individuality (both of the doctor and of the patient) shall be preserved—the more the better; but there will be a residuary service (assumed to be one-third), which must be done collectively. The money, therefore, must be apportioned accordingly. That is all.

There will, however, be room for the exercise of charity, and that of the most refined kind—the kind that does not let the right hand know what the left hand doeth; and there will be opportunity for the performance of public professional service of a very high order. These are points in the scheme worth noting, and they do not stand alone. Indeed, I have from time to time observed how readily this simple plan adapts itself to the various requirements of the present day, and is ready, as in the present instance, to put an end to what you characterise as "an unseemly and paltry squabble" about fees; or as I should be disposed rather to classify it with those confessedly difficult and perplexing problems of advice gratis, hospital abuses, counter-practice, quackery, and various other professional "grievances", for which the same plan would serve, and for which no other remedy worth the name has been as yet discovered.

These incidental confirmations of the soundness of my plan have inspired me with confidence that otherwise I should not have presumed to express.—I am, yours faithfully,

WILLIAM OGLE.

Derby, February 11th, 1878.

SIR,—The plan of Dr. Ogle of Derby, mentioned in the leading article in the BRITISH MEDICAL JOURNAL of February 2nd, of substituting annual subscriptions for separate fees, reduced to practice, means a medical club for the middle and upper classes, and would sacrifice the independence, and consequently the dignity, of the profession to the disadvantage of both parties to it. I would not again work under such a plan, for any class of the community, for ten times my present small income, obtained by charging separate fees according to the ordinary graduated tariffs of this and other districts. Patients would still be discontented; but the "haggling" would be transferred from the amount of their bills to the amount of attention they would consider they required or were entitled to. For my own part, patients never "haggle" with or cheat me a second time. I am strongly in favour of medical clubs on an equitable basis; but the present system, whereby the work required for a very small given sum is an unknown quantity, is a commercial (I use the word in its strictly economical sense) anomaly, and cannot be too strongly condemned. I have studied this subject of club medical aid *versus* separate fees attentively, and am inclined to say more, but trust that those who are enamoured with the beautiful simplicity and good intention of Dr. Ogle's plan, will seriously consider its grave defects. We should be in danger of losing the moral control of our patients and our own self-respect; we should, in fact, be in the position of paid servants, without any redeeming or counterbalancing *prestige*: to say nothing of the extra work and worry, for probably less than the present insufficient remuneration.

A short time since, we were told that the profession had given its cordial sanction to self-supporting hospitals for the middle classes. Unimportant as my influence may be, as an unit of that profession, I protest against any such *unimpaired* interference with my bread winning occupation. I regret troubling you; but plans like these, seriously

affecting the vital interests of the profession—and, therefore, of the public—require free discussion.—Yours faithfully, W. J. MARSH.  
Shrewsbury, February 9th, 1878.

SIR,—For years past, it has been a matter of surprise to me that our profession could rest content with the anomalous condition of its different grades, and that the "one portal" question could be discussed, and almost settled, without a thought being directed to the legal or ethical status of the members after their admission into the profession. Accordingly, I hailed your "leader" and the correspondence following it as the key-note of a much needed reform.

It has always appeared to me that there ought to be a very broad line of distinction between consultants and ordinary practitioners; not only in the matter of remuneration, but in the lines of practice open to them respectively. It matters not to what branch of practice a man devotes himself, he cannot or ought not to be at once a consultant and an ordinary practitioner. It is essential to have two classes, as distinct as barrister and attorney; but it is equally essential that there should be no possibility of competition between them. At present, there is no distinction, but universal competition. The same man is consultant in one house and general practitioner in another; his fees are sometimes honoraria, sometimes matters of account; and the fees of the general practitioner are often as large as those of the consultant for ordinary attendance. How is this to be obviated?

I venture to suggest that the Medical Council should take steps to separate the two classes, somewhat in this manner. The consultant should hold a special diploma; undergo a special course of study; and give evidence, in public gratuitous practice (hospitals), of his qualification for the position to which he aspires. A central authority should then have power to license or "call" him to practise as consultant in the special branch to which he has devoted himself. His practice should consist in giving counsel and advice, in consultation with general practitioners; and he should be precluded from holding communication with any patient, except through general practitioners. His fees should be honoraria, and not recoverable at law.

On the other hand, the general practitioner (so called until a better name is coined), holding certain diplomas, should be allowed to engage in one or all the branches of practice, and should be the ordinary medical and surgical adviser in all cases. He should be obliged to take out an annual licence to practise, which should give him a legal status to recover debts for professional service, in accordance with an established scale of charges. Such a scale would not prevent his charging more or less, according to circumstances; but would fix the amount recoverable at law, and so form a data for ordinary charges.

Such a division would correspond somewhat with barrister and attorney-at-law, and would be returning very much to the position of the profession in the last generation, when the apothecary was the ordinary attendant, and the physician or surgeon was called in to advise in difficult cases. It might possibly, at first sight, wound the susceptibilities of the more aspiring; but this is a matter of small moment compared with the advantage to the profession at large. There would be no longer any jealousy between the consultant and general practitioner. The former could not, if he would, be a competitor with the latter; and consultations would be more frequent, more cordial, and better paid than they are at present. There would be some reason then (and an explanation to the public) for men spending so much of their time in hospital and other gratuitous work, when it became necessary for them to prove their competence to fill the lucrative position of consultants. Professors or teachers would be drawn exclusively from their ranks, and many appointments would be open only to them; while the general practitioners would have all the family practice, with a legal basis for their charges.

I refrain from entering into details out of respect for the space in your columns, and am, sir, yours,  
EDWARD CROSSMAN.

Hambrook, near Bristol, February 4th, 1878.

#### CATGUT-DRAINAGE.

SIR,—Mr. Bradley, in his paper on Antiseptic Surgery (February 23rd, 1878), speaking of drainage, says, "Chiene's catgut method of drainage, which acts by capillary attraction, is perhaps the most inefficient of all". Mr. Bradley does not give his grounds for this assertion. I ask him to do so in your JOURNAL.—Yours, etc.,  
EDINBURGH, February 25th, 1878. JOHN CHIENE.

DONATIONS, ETC.—E. A. S. has given £100 "In Memoriam", to found a bed in the Cripples' Home, Bray. The late Edmund Burke of Cork has bequeathed £50 to the North Infirmary, Cork, and a similar amount to the Mercy Hospital in the same town.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### A CONSTITUTIONAL QUESTION.

THE correspondence which has taken place between Mr. Buck of Newport, Essex, the Board of Guardians, and the Local Government Board, raises points of such importance to all Poor-law medical officers whose stipends are arranged in accordance with the Consolidated Orders, that we shall briefly comment on it. It would appear that, in April 1877, Mr. Buck was ordered by the relieving officer to visit two of the children of a labouring man named Wright, who were affected with bronchitis. Their names were duly entered in the medical relief-book, and they were attended until well, no objection being raised at that time to the propriety of such attendance. That the relieving officer was justified in giving such an order, is evident from the fact that Wright has seven children, the eldest aged only fourteen; this one, a girl, earns one shilling a week and her board; a younger one earns three shillings a week; the united earnings of the family—out of which rent, clothing, and food have to be found—amounting only to seventeen shillings a week.

In December last, Mr. Buck was called to attend one of the same children, whose leg was fractured. On the father applying to the relieving officer for an order, it was refused; that official, however, permitted him to apply to the Board of Guardians, but with no better success. Thereupon Mr. Buck wrote to the Board, requesting to know the reason why they refused to grant an order in December when one was sanctioned in April. After three several applications, he received, on the 16th ultimo, a letter through their clerk, simply acknowledging the receipt of his three letters. Not daunted by this, Mr. Buck again wrote, and demanded an explanation of their action in granting an order for medical attendance in April and refusing it in December, the circumstances of the party remaining the same. In their reply, the Guardians state "that they consider the case in no way altered, and adhere to their former opinion (when expressed does not appear), that is, that Wright's case was not one that called for assistance from them".

Whilst this correspondence was going on, Mr. Buck wrote to the Local Government Board, giving the facts of the case, and inquiring whether, having ordered his attendance on the family in April, the guardians could refuse an order in December. He received for answer that the guardians were the sole judges when an order for relief, medical or otherwise, should be granted; that if an order for medical relief were granted, such order only remained in force so long as the illness continued; and, therefore, an order for relief given in April would not apply to a fracture of a leg of one of the children in the following December; but expressing no opinion on the fairness of the guardians towards him.

Now, we can have no hesitation in expressing our decided opinion that Mr. Buck has been most meanly used by this Board of Guardians; for it will be noticed that, when medical relief pure and simple is ordered for Wright's children, no objection is raised; directly, however, that an accident occurs, the treatment of which involves a fee of £3, then the order is refused. Our readers will also not fail to observe that the Local Government Board do not give any opinion on the merits of the case, beyond stating that the guardians are the sole judges when relief should be afforded. Seeing, however, that Mr. Buck holds office under the provisions of the Consolidated Orders, we are of opinion that successful action could be taken in the County Court for recovery of the fee; at any rate it would be worth the trial, as it would determine the legality or otherwise of a board of guardians directing their medical officer to attend a case of ordinary illness, and refusing the same when such attendance carried with it a fee.

We would also advise Mr. Buck to get a question asked in the House of Commons on the subject, upon the framing of which question we should be very pleased to advise him, if he should make application to us.

### POOR-LAW MEDICAL APPOINTMENTS.

MACLAUGHLIN, F. P., M.B., appointed Medical Officer of the Strangford Dispensary District of the Downpatrick Union, *vice* W. Chartres, L.K.Q.C.P.I., resigned.  
THOMSON, J. A. Mulville, L.K.Q.C.P.I., appointed Medical Officer to the Workhouse and Public Vaccinator, Newport (Salop) Union.

## PUBLIC HEALTH MEDICAL APPOINTMENTS.

HARVEY, H., M.B., appointed Medical Officer of Health for the Township of Wavertree (Liverpool), *vice* James Legros, M.R.C.S., deceased.  
PRICE, J. Le, M.R.C.S.E., reappointed Medical Officer of Health for the Standish District.

## TREATMENT OF THE POOR AT GLOSSOP.

SIR,—In reference to your article in the JOURNAL of last week respecting the above, allow me to say that the out-door medical relief cases of the adjacent villages to Colchester are equally heathenly treated; and I have no hesitation in saying that, were it not for the kindness of the medical officer of health, who, I am informed, now relieves some of the distress by visiting, giving medicine, etc., as well as kind words (which are quite foreign to that district), the poorer classes would suffer far more than any one could imagine in this enlightened quarter of the globe, where it is supposed that the clergy, medical officers, and other high public servants are only too happy to minister to the wants and necessities of their fellow creatures.—I remain, yours, etc.,

MARTIN LUTHER.

## MILITARY AND NAVAL MEDICAL SERVICES.

INDIAN MEDICAL SERVICE.—The following is a list of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination held at Burlington House, on the 11th February, when thirty candidates competed for twenty-five appointments, and all were reported qualified. [One appointment was subsequently added.]

## MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Licentiates on February 22nd, 1878.

Batty, John Howard, 123, St. George's Road, S.W.  
Bennett, William Charles Storer, 17, George Street, Hanover Square, W.  
Blaxland, Herbert, University Hospital, W.C.  
Chawner, Alfred, 73, Addison Road, Kensington, W.  
Coates, Harcourt, 8, Granby Street, N.W.  
Griffith, Charles William, Station Hospital, Dover  
Harris, George Francis Angelo, 55, Sutherland Gardens, W.  
Pearse, Thomas Frederick, 62, Haverstock Hill, N.W.  
Pointon, James, Birkenhead  
Ritchie, Arthur Fisher, 13, Charlotte Street, W.C.  
Sykes, John Frederick Joseph, 20, Fitzroy Square, W.  
Turner, George Robertson, 9, Sussex Gardens, W.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, February 14th, 1878.

Evans, Robert Davies, Criccieth, North Wales  
Reddy, Herbert Lionel, Montreal

The following gentlemen also on the same day passed their primary professional examination.

Bishop, James Thomas, Guy's Hospital  
Jago, Edwin Osborne, Guy's Hospital  
Morgao, William Pierce, Guy's Hospital  
Nourse, William John C., St. Mary's Hospital

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual monthly examination meetings of the College, held on Tuesday, Wednesday, and Thursday, February 12th, 13th, and 14th, 1878, the following candidates were successful.—For the Licences to practise Medicine and Midwifery.

Allen, Edmund Henry  
Collins, Patrick John  
Curran, Thomas John  
Emerson, John Joseph  
Hamilton, John Robert  
Leary, Edward George  
Mackay, William Brittain  
Wride, Francis George

For the Licence to practise Medicine.

Flannery, James Gordon

Hassard, Richard John

For the Licence to practise Midwifery.

Love, Robert Lindsay

## MEDICAL VACANCIES.

THE following vacancies are announced:—

BALROTHERY UNION—Medical Officer of Lusk Dispensary District. Salary, £125 a year as Medical Officer, and £20 16s. 8d. as Sanitary Officer, with the usual Registration and Vaccination Fees. Election will take place on the 2nd instant.  
BROMYARD UNION, Parish of Cradley—Medical Officer and Public Vaccinator. Salary, £50 per annum, and fees. Applications to be made on or before the 9th instant.  
GENERAL INFIRMARY, Hertford—Medical Resident and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before the 6th instant.  
GORT UNION—Medical Officer of Ardahan Dispensary District. Salary, £140 a year as Medical Officer, and £10 as Sanitary Officer, with Registration and Vaccination Fees. Election on the 14th instant.  
KENSINGTON DISPENSARY—Resident Medical Officer. Salary, £105 per annum, with furnished apartments, coals, gas, and attendance. Applications to be made on or before the 4th instant.  
KILLALA UNION—Medical Officer of Killala Dispensary District. Salary, £60 yearly, and £20 as Sanitary Officer. Applications to the 2nd instant.  
NARBERTH UNION—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.  
PUBLIC DISPENSARY, Stanhope Street, Clare Market—Resident Medical Officer. Salary, £105 per annum, with furnished apartments, coals, and gas. Applications to be made on or before the 4th instant.  
SLIGO UNION—Medical Officer for Carney Dispensary District No. 2. Salary, £120 per annum as Medical Officer, and £20 per annum as Sanitary Officer, with the usual Registration and Vaccination Fees. Applications to the morning of the 13th instant.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

## MARRIAGE.

FORT—MELLOR.—On February 20th, at the Parish Church, Oldham, Thomas L.R.C.P., M.R.C.S.L., L.M., to Annie, youngest daughter of the late J. Haque Mellor, Esq., of Falcon House, Oldham.

## DEATH.

TREDENNICK, William Magee, M.D., youngest son of the Rev. G. N. Tredennick, formerly Vicar of Kilbarrow, co. Donegal, at Shanganagh Terrace, Ballybrack, co. Dublin, aged 32, on February 26th.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The fifth meeting of the twenty-second session was held at the Royal Kent Dispensary, Greenwich Road, on Friday, February 1st; W. Johnson Smith, F.R.C.S., President, in the chair. Dr. B. Peacock read a paper on some cases of Pleural Effusion. The next meeting will be on Friday, March 1st, at 8 P.M., when Dr. A. L. Galabin of Guy's Hospital will read a paper on Operative Measures in Congenital Atresia Vaginae.

PRESENTATION TO DR. J. ORSBORN.—On Thursday, February 14th, a service of plate was presented to Dr. Orsborn of Bitterne, at the South-Western Hotel, Southampton, as a mark of esteem from a numerous body of friends on his relinquishing practice. The presentation comprised a salver, a suite of "apostles" spoons and salts, a service of small plate in chest, and a fish and dessert service; the whole being of solid silver and chastely engraved, and bearing also the crest of the recipient. The total subscriptions from about one hundred and twenty subscribers, many of whom were patients in humble circumstances, amounted to a trifle over £260. The salver bears the following inscription: "Presented, with a service of plate, to John Orsborn, Esq., M.D., by his friends and neighbours, on his retiring from practice. A.D. 1878." Along with the plate, the following address was presented. "To John Orsborn, Esq., M.D., M.R.C.S., etc. We whose names are inscribed hereon, having heard of your contemplated retirement from the active and arduous duties of your professional practice, from which, combined with your skillful knowledge and uniform kindness, many of us have experienced and derived the comfort and alleviation so needful to us in the hour of sickness and affliction, beg to tender you our sincere and heartfelt wishes for your future health, happiness, and prosperity; and to assure you that, although you are about to remove from the sphere in which you have devoted so many years of your well-spent and useful life, whereby we shall necessarily be deprived not only of your professional services and assistance, but of the social intercourse which it has been our privilege and pleasure so long to enjoy, you will carry with you the regard and approbation of your numerous patients and friends, to which you are so justly and honourably entitled. With this memento, and in appreciation of your distinguished qualities and the talent you have so conspicuously displayed during your successful career, we also desire your acceptance of the accompanying testimonial—a tribute intrinsically of small value, but a token expressive of our sincerity, respect, and esteem."

## OPERATION DAYS AT THE HOSPITALS.

MONDAY..... Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

TUESDAY..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY.. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

THURSDAY.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

FRIDAY ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

SATURDAY.... St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London. Annual Meeting. At 7.30 P.M., Election of Officers and Council; Ballot closes at 8.30 P.M. Dr. Howard, U.S.A., will give a demonstration of the "Direct Method of Artificial Respiration"; Mr. R. Brudenell Carter, "On Artificial Light in relation to the comfort and well-being of the Eyes".

TUESDAY.—Pathological Society of London, 8.30 P.M. Dr. Goodhart: Dilatation of the Heart and Aorta from old Spinal Disease. Mr. G. C. Coles: 1. Lymph Scrotum; 2. Worms in the Heart and Esophagus of a Dog. Mr. B. Squire: 1. Drawing of a rare form of Psoriasis; 2. Drawing of a case of Nævus complicated with Molluscum. Mr. Sangster: Case of Hypertrophic Lupus. Dr. Ord: 1. Renal Calculus containing Indigo; 2. Renal Calculus of mixed Carbonate and Phosphate (from the same subject); 3. Two specimens shewing the Spontaneous Disintegration of Calculi. Mr. Spencer Watson: 1. Polypus from the Antrum and Orbit; 2. Colloid Cancer of the Breast. Mr. Nunn: Sections of Tumour from the Pectoral Region of a Man, aged 57.

WEDNESDAY.—Obstetrical Society of London, 8 P.M. Specimens and Instruments: Dr. Hayes, Tube for Intra-uterine Injection of Solution of Perchloride of Iron; Dr. Galabin, Metrotome; Dr. John Williams, Uterus with portion of Placenta, three weeks after labour. Papers: Dr. Matthews Duncan, "On Traction by the Lower Jaw in Head-latch Cases"; Dr. George Roper, "Case of Protracted Labour in which the Forceps was typically indicated"; Royal Microscopical Society, 8 P.M. Mr. Adolf Schulze, "On an easy and simple method of resolving the finest lined Diatomaceous Tests"; Mr. Chas. Stewart, "On a supposed new Coral".

THURSDAY.—Harveian Society of London, 8 P.M. Casual Communications. Dr. T. S. Dowse, "On the Treatment of Syphilitic Disease of the Nervous System"; Linnean Society (Burlington House), 8 P.M. Dr. Patrick Manson, "On the Development of *Vibrio Sanguinis Hominis* and on the Mosquito considered as an intermediate host"; Dr. T. Spencer Cobbold, F.R.S., "The Life-History of *Pilaria Bursaria*, as explained by the discoveries of Wucherer, Lewis, Bancroft, Manson, and others".

FRIDAY.—Clinical Society of London, 8.30 P.M. Mr. Hulke, "Large Aneurysm of Left Subclavian and Axillary Artery treated by rest and a very restricted diet" (living specimen); Dr. Broadbent, 1. "Sudden Death from Effusion into the Pleural Cavity, without Paracentesis"; 2. "Unusually rapid Effusion of Bloody Fluid into the Pleural Cavity, at the age of 76: Paracentesis: Recovery"; Dr. Frederick Taylor, "Unilateral Atrophy, with Muscular Spasm [Athetosis?] (living specimen)".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

THE following communications have been handed to the General Manager:—Mr. J. C. Garman, Wednesday; Mr. B. Brown, Manchester; Dr. Hayden, Dublin.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

ADVERTISERS are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the JOURNAL Office or any stated address other than a Post Office.

## DR. BURDON SANDERSON'S EXPERIMENTS.

SIR,—Perhaps Dr. Sanderson will kindly add to the obligations he has conferred on the profession by supplementing his account of the paraffin experiment (see BRITISH MEDICAL JOURNAL, January 26th, 1878, page 119) on the following point. I shall be glad to know (I am sure with many others) what were the morphological characters of the objects described by Tiegel and Billroth in 1874, and by the learned lecturer this year. If the bacteria were in the form of rods or "colonies" of spheroids, we may, I presume, consider the question of their existence in these conditions as established; but if the appearances so described were isolated moving spheroids, there will still be found sceptics who doubt the possibility of distinguishing by microscopical characters minute fatty and other granules from spherical bacteria. Most of us have no means of referring to Tiegel and Billroth's original publications, and we shall in any case be glad to know in what forms Dr. Sanderson found the bacteria in his experiment.—I am, yours faithfully, M.D.

## THE TELEPHONE IN FEVER-HOSPITALS.

SIR,—A suggestion, which seems to be of considerable practical value, has been made to me by a lady who has lately had one of her sons confined in a fever-ward; and, with the lady's permission, I send the suggestion to you. It is, that the instrument in question should be used for convalescent patients within fever-wards to converse with their friends, to whom immediate access is necessarily denied on account of infection. A telephone can easily be carried from bed to bed within a ward, and the corresponding instrument might be fixed in any office at a distance. Possibly, if the arrangement were found serviceable, the proprietors of the patent for the telephone might see fit to supply the instruments to hospitals at a less cost than that charged for those employed for commercial purposes.—I am, etc., February 1878. M.A. Oxon., F.R.S.

## MEDICAL ETIQUETTE.

SIR,—In Dr. Beresford's letter to me, published in my statement in the JOURNAL of December 6th, he says about Morris's arm: "I found the arm very much deformed and its utility impaired; in fact, it was so angular, that the most unskilful observer would have pronounced it a very crooked fracture." In his letter to you, published in the JOURNAL of January 12th, he admits that the radius was well united, and could not have been interfered with by his manipulation. Is it any wonder that I expected him to reconcile these two statements, and that I have asked him to state specifically what there was the matter with the arm that induced him to take this man into hospital, to risk his life under chloroform, and to keep him there, against rule, at the expense of a not very rich charity? what he did to remedy the evil, and how he did it?

Dr. Beresford calls it a trivial case—too trivial to trouble a colleague about (see his first letter)—but I think that a case that would justify Dr. Beresford acting as he has done is not a trivial case, either for the patient or for me, and certainly not for Dr. Beresford. Dr. Beresford carefully avoided meeting me at Shrewsbury (see also his first letter). He has closed his case by carefully avoiding answering my questions. I have nothing further to say, and I now leave the case in your hands.—I am, sir, yours obediently, W. H. Box.

Chirk, February 25th, 1878.

\*. The correspondence must now cease. Mr. Box must feel that he has amply vindicated his professional character; and the profession generally will not have failed to have formed their opinion of the conduct of which he has justly, we think, warmly complained.

## BOOKS, AND ILLUSTRATIONS IN THEM.

SIR,—It would, I think, be a great advantage to us in many respects if our medical publishers would cut the books before leaving the press, as in America. We should then have neat looking volumes on our bookshelves, instead of the ragged edges which attract the dust, not to mention the loss of time to the busy practitioner in cutting them. Again, with regard to illustrations, which are of undoubted value in enabling the reader to comprehend what no written description could possibly make so clear. Photography is now extensively used for exhibiting cases at medical societies; but for book illustration it is a very expensive method, besides that the photograph in after years becomes yellow, and ultimately indistinct from the action of light, or of the hyposulphite of soda which is used in finishing, and which is difficult to entirely wash out of the print. But an engraving on either wood, stone, copper, or steel, cannot be compared to the truthful representation by photograph. Except those who study the photographic art, I think there are few who know of the great advancement it has made in the subject of permanent photography or "photographs in printers' ink." I will not now enter into the details of this process, but will briefly remark the names of the two methods—viz., the Woodburytype and heliotype. These methods are also less expensive than ordinary woodcuts, each engraving costing about threehalfpence per copy. Mr. Briggs of Baker Street has been very successful with his process. The portraits of insane patients in the late Dr. Thompson Dickson's work on *Mind in Relation to Disease* were by him. Several other works have also been illustrated by permanent photography, but it is not so generally adopted as I think it deserves to be. I trust these few remarks may attract the attention of both authors and publisher.—Very truly yours, February 1878. GEORGE CHARLES COLES.

SIR,—It is a very prevalent belief amongst females (both rich and poor) that, in curing hams, women should not rub the legs of pork with the brine-pickle at the time they are menstruating, or the hams will go bad. I shall be glad if any of your readers can tell me if this be mere imagination, or if such be really the case, and if so, how it is to be explained. I have seen it twice tried, and both times the hams did go bad; but whether this was in any way due to the menstruation I cannot tell.—I am, sir, yours faithfully, A MEMBER.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### JUDICIAL POST MORTEM EXAMINATIONS IN SCOTLAND.

SIR,—Having read your remarks in the BRITISH MEDICAL JOURNAL of February 9th, on the unpublished correspondence of Dr. Angus Fraser, which raises the question of the duty of the Procurator-Fiscal in issues that affect the medical profession in common with the general public, I have a complaint to make, which more nearly concerns the members of our profession themselves, on which I desire to solicit your opinion. I was some time ago called to see a man who had come home intoxicated, had fallen down the stairs of his own house, and, judging from the symptoms, had fractured the base of his skull. I visited him twice the night he fell, and twice next day. On the day of his death, I saw his friends, and told them I would make a *post mortem* examination that day at one o'clock, to which they readily consented. On proceeding to his house with an assistant at the hour appointed, I found the door locked; and, on inquiring the cause of a neighbour, was told that the police, who had been there before me, had locked the door and given orders that no one should be admitted, as the surgeon of police himself would perform the necropsy that afternoon. Considering the man a patient of my own, I confess I felt somewhat indignant, having received no notice that such an examination was contemplated.

I would not have brought forward this case, had it not been that medical men in Aberdeen have not unfrequently of late had to complain of similar treatment. In cases where a judicial investigation is required, many of us here are of opinion that it would only be a matter of common courtesy to request the presence of the ordinary medical attendant; indeed, we think he should always (unless in some exceptional cases) be conjoined in the remit with the medical expert.—I am, yours truly,

Aberdeen, February 23rd, 1878. JAS. D. WYNESS, M.D.

\*. If the Procurator-Fiscal were aware that our correspondent had attended the deceased immediately before death, we think that he should have handed the remit for a *post mortem* examination to him, or at least, as a matter of courtesy, have requested him to attend and perform the necropsy with the surgeon of police. Coroners and Procurators-Fiscal have the power to nominate any surgeon to make the *post mortem* examination; but this power should always be exercised with discretion. In this case, we cannot see that there was any circumstance to justify the *post mortem* examination being handed to a stranger.

#### TURPENTINE IN POST PARTUM HÆMORRHAGE.

SIR,—Mr. Pollard's letter in this day's JOURNAL reminds me of a case I met with many years ago, and which I shall never forget. I was sent for in a great hurry to see a dispensary patient, and declined to visit her, as the dispensary medical officer had been sent for. The messenger replied, "I believe, sir, she will be dead before he comes". I went at once, and found the woman pulseless and quite insensible from loss of blood. I sent for some turpentine immediately, and with difficulty got down half a teaspoonful with an equal quantity of milk—rather a stiff dose. It saved her life, but she had no recollection of taking it. The midwife to a lying-in charity with which I am connected always takes turpentine with her, and never hesitates to give a dose if she thinks it is required. I believe a slight stimulant after delivery never does harm. Turpentine is not so expensive as the aristocratic brandy and egg, which I always administer on these occasions, and which ladies much appreciate; nor are they likely to take it for the love of drinking as they might other stimulants.—Yours, etc.,

Clifton, February 23rd, 1878.

#### VOLUNTEER SURGEONS.

APPLICATIONS for examination must be made through the commanding officer to the Assistant Adjutant-General of the district. The examining board consists of the principal medical officer of the district and two other army officers. The form of certificate is as follows.

"We certify that — of the — (who is registered under the Medical Act of 1858 as qualified to practise medicine and surgery in Great Britain and Ireland) is well acquainted with the nature and intended application of the various articles comprising the equipment of Army Hospitals in the field, and with the authorised means for the transport of sick and wounded soldiers, and the proper modes of employing them. We also certify that he has a competent knowledge of the treatment of the wounds and injuries to which troops are liable in the field, particularly with regard to the special circumstances of campaigning; and that he is acquainted with the duties to be performed by army medical officers in camps and bivouacs, and during marches, as named in Section 21, Sanitary Regulations for Field Service, pages 82, etc., of the Official Code of Army Hospital Regulations."

This certificate indicates sufficiently the subjects with which the candidate should be acquainted. Intending candidates for examination, in addition to possessing the knowledge derivable from the ordinary standard text-books on medicine and surgery, should study the following:—Parker's *Hygiene*; Longmore on *Gunshot-Injuries*; Longmore on the *Transport of the Sick and Wounded*; Porter's *Surgeon's Pocket-Book*; the *Manual of Instructions for the Officers and Men of the Army Hospital Corps*; and the *Army Medical Regulations*.

#### LOCUM TENENS.

SIR,—It would be satisfactory to know the opinion of the medical profession on the following questions, since I believe engagements, as a rule, between the *locum tenens* and the medical agent are not defined accurately, and often lead to many grounds of complaint. 1. When an agent engages a *locum tenens* to take charge of a practice, is that agent responsible to the principal if the *locum tenens* defraud the principal? 2. When an agent engages a *locum tenens* to take charge of a practice, is that agent responsible to the *locum tenens* if his expenses and salary be not paid by the principal? It is only fair to state, that both principal and *locum tenens* pay an office-fee of *ros. 6d.* to the agent for each engagement. What do they pay the fee for? To know this, in my opinion, is most important to principal and *locum tenens*.—Yours faithfully,

M.D.

SIR,—A correspondent, through the JOURNAL of the 9th instant, inquires whether there be an English translation of Bouchut's *Traité des Maladies des Enfants*. Dr. Peter Hinckes Bird translated the work, with notes and additions, and published it in one thick volume, in 1855.—I am, etc.,

16, Bloomsbury Street, London, February 9th, 1878. E. N.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### PHYSICIANS' FEES.

SIR,—I quite agree with a "Country Surgeon", who in your issue of February and supports the suggestion that "some fair and reasonable scale of fees should be arranged either by the General Medical Council or by the British Medical Association, and that steps be forthwith taken for their universal adoption by the profession". Many of us rejoice with the "Country Surgeon" that "the subject has at length been taken up", for it is only by vigorous and united action that we can obtain our rights from the public; and to do this, we must turn our Association into an "union", in the best sense of the term, adopting an organisation for making ourselves better paid and respected than at present. Let us do nothing gratuitously, for people put no value on what they obtain without cost. But there must be no tinkering; we must back up the policy of the British Medical Association from beginning to end. The "one portal" scheme of entrance to the profession must be strenuously and continuously supported, while examining boards must be encouraged to pluck candidates freely, so as to prevent the profession from being overstocked, and to put an end to the disgraceful competition which now exists by means of "gratuitous advice" and "open surgeries".

Charity begins at home. Why should I treat another medical man gratuitously? *A fortiori*, why should I so treat his wife and children? The custom exists in no other profession; so let us abolish it at once, to show the public we are in earnest in refusing to work for nothing. A clergyman who is absent on Sunday has to give another clergyman two guineas to do his duty for him, and very often he pays his substitute's expenses in addition. No lawyer gives his opinion to another without charge; and imagine his amazement if he were requested to give any one gratuitous advice on the plea of relationship to a professional opponent! I know medical men in their inmost soul object to the present system; for, when my wife and I were both ill, we were very badly attended till we got advice elsewhere and paid for it, not letting the man at the strange place know we belonged to the profession, and the improvement in attentiveness was most marked.

Why should death-certificates and club-certificates be given gratuitously? No clergyman gives a certificate of baptism without a fee; and it is far more trouble to fill up a death-certificate properly than one of baptism. Gratuitous advice should be given only to the really poor, at hospitals and workhouses, or in connection with very carefully managed dispensaries. At the same time, I own there are people who cannot pay ordinary fees, and whose social position prevents them from going to hospitals or dispensaries; so I respectfully beg leave to submit a suggestion for treatment by contract, to be discussed by the profession.

In India, there are hardly any medical men but the Government surgeons, who are paid by Government to treat all Government officials and servants; but these must pay for the treatment of their families, unless they are military officers doing military duty. Military officers in civil employment, drawing more than a certain salary specified by Government, must pay like civil officers for their families; and the custom sanctioned by Government is to give the surgeon a week's pay for a year's treatment, and this is paid whether the family is ill or well: I mean a week's pay reckoned out of the officer's salary, not the surgeon's. As all sorts of officials are constantly being moved about, it comes to be agreed that these officers give the surgeon half a day's pay per month, either annually or when he or they leave the station. The patients must get their medicine at the druggists at their own expense. But we must remember the surgeon draws a substantial salary from Government for treating his male patients, so that his fees for women and children are mere extras; and allowance must be made for this in estimating what contract a surgeon in England could afford to offer his patients, though I suppose a low rate would suffice when we consider what miserable payment is given by benefit clubs. The week's pay in India for the year's treatment is for only ordinary treatment. Confinements are extra, the fee varying from fifty to three hundred or more rupees, according to the means of the patient's husband. For casual visits or consultations, where no contract exists, the fee is one gold mohur, or sixteen rupees, say thirty-two shillings; for night visits, two gold mohurs.

If the system were introduced in England, a surgeon might contract with his less wealthy patients to attend a man and his family for one day's pay per month, payable monthly. The man's monthly subscription to the benefit club should be reduced, and thus the present touting for club practice would be abolished. We should no longer hear of a club dismissing Mr. A., who has been paid £50 a year many years for careful and conscientious treatment of its members, because some rascally Mr. B. had disgracefully undersold Mr. A. by offering to do the duty for £45. At the same time, if surgeons enforced the rule that no treatment could be given if the subscription were in arrear, I believe they would, on the whole, gain rather than lose by the abolition of clubs. The club-members would often prefer this arrangement, for they frequently complain of being obliged to go to the club-surgeon, and employ some one else in whom they have more confidence to treat their families. The monthly subscription should be for only ordinary attendance by daylight. Medicine should be obtained from the druggists in towns. In the country, a surgeon should supply it at a price sufficient to cover his expense in obtaining it, making it, and conveying it; but this charge should have nothing to do with that for advice. Confinements and major operations should be the subjects of extra charges. For major operations, the charge would vary with the difficulty of the operation and the means of the patient. Minor operations, like vaccination, tooth-drawing, and opening small superficial abscesses, should be included under "ordinary treatment". For a confinement, the patient might be called on to give at once a week's pay of her husband's income as an extra charge. Night visits should cost a day's pay extra, paid at once. Most night visits are unnecessary. The night visit should mean any visit paid before the surgeon's breakfast, and after sunset, or after the surgeon's dinner, if he dine late.

Consultants should abstain from private visiting practice, and be consultants purely, whether medical or surgical, taking their fees at the moment. Special arrangements must of course be made for ovariectomy and other important operations. Strictly speaking, a consultant should see no patient except in consultation with the family-surgeon, or on receipt of a note from him presented by the patient; but perhaps opinion is hardly yet ripe for this.

The senior consultants should refuse single guinea fees, leaving them to the juniors, and should act like barristers who are "leading counsel", taking only high fees which should be fixed by arrangement beforehand between them and the family-surgeon, thus giving a consultant the option of saying he was "too busy to take the brief" if the fee were too low for a troublesome case, details of which should be explained by the family surgeon, as it is a waste of time for the consultant to be obliged to make out for himself the character of the urine, the temperature, pulse, respiration, measurements, and similar details of routine.—I am, sir, your obedient servant,

A JUNIOR.

## THE BRITISH MEDICAL ASSOCIATION.

SIR,—As one who signed the circular and answered "No" in regard to the admission of ladies to the membership, perhaps you will allow me to say that after the leader of February 16th on the lady question, Dr. Wilson Fox may with every propriety reconsider his withdrawal—at least for a time—from the Association. There is another matter of far more vital importance than the admission of ladies, and that is, the fact of the Committee of Council taking upon themselves the office of printers, and going to expend £2,000 of the money of the Association without one word having been said at the last annual meeting, or any intimation having been given to any of the members. Besides, sir, it appears from a letter of Dr. W. G. Grigg, secretary of the Metropolitan Counties Branch, that the proceedings of the Committee of Council of January 6th are suppressed to such an extent that Dr. Grigg says they are "marred by large omissions". Should this be so? Who is to blame? Surely not the editor, Mr. Ernest Hart? The whole business of the Association requires careful looking after; and if Dr. Wilson Fox and others who know much of its workings resign over the question of the admission of ladies, and ignore other vital matters, there must be a collapse. After the taunts and gibes so freely indulged in towards the two lady members—Mrs. Hoggan and Mrs. Anderson—their husbands should, out of sheer shame, induce them to resign. It was quite clear that Mrs. Anderson was out of her sphere at the last meeting of the Association in Manchester, and she was only laughed at and formed a butt for all kinds of jokes. They are not wanted, and should not intrude. Seeing that the Association is an irresponsible body, and by its vote has condemned the presence of ladies, they should accept that vote, and retire. If they do not, Dr. Wilson Fox, before the next meeting, should give notice, so as to bring the question forward as soon after the opening meeting as possible, and he will be supported; but in the meantime he should reconsider his resignation, and not sever himself from the Association at this very critical moment.—I am, &c.

Northallerton, February 18th, 1878.

\* The reports of the proceedings of the Committee of Council are purely official, and are furnished by the General Secretary and published in the official column of the JOURNAL, in connection with which the editor, who is not present at the meetings of the Committee of Council, has no responsibility.

## THE ADMISSION OF LADIES TO THE MEETINGS OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—It seems that rational arguments against the admission of women to the profession now fail: that those which have hitherto been employed are proved by facts to be fallacious; and that it only remains to the opponents of women-doctors to "pity and despise" them. This course (which is, by the way, essentially a weapon of feminine warfare) is at all events that now adopted by Dr. Wilson Fox. He invites the opinion of members of the Association upon a question which he thus states:—"How far public discussion upon medical topics at which men and women are present, and upon which no restrictions are placed, are consistent with the rules of propriety and delicacy which have hitherto been generally held to obtain in the relations between the sexes?"

I demur to any proposal to open up this question afresh in a manner which premises the presence of an element of sexuality in it. Women are not as men in respect of sexual feeling. Men naturally judge women by their own feelings in this matter; yet it is none the less a mistake for men to extend the modes of thought and action, which are by nature rendered necessary in matters sexual, to matters which do not directly involve sexual feeling. If men will leave this view of the subject alone, women will not suggest it. It is contrary to their nature to suggest it, although, just as naturally, they will recognise it when it is placed before them; and that is why the onus of seduction lies on man.

Now, that is very plain speaking, and some apology for it is due. The apology is, that it is men who have introduced this element into the discussion; that it is men who have professed to fail to distinguish between sex and science; that it is men who, after throwing every legitimate obstacle in the way of women who desire to study this branch of knowledge, have at last said, "We think for you" (?). Does any one know so little of women as to suppose that had men been seeking admission to this profession in their hands, the most strenuous opposition would in its last extremity have taken this form? Indeed, I begin to see reason to be thankful for what, hitherto, I have taken as a matter of course—that I can hear without apprehension whatever a woman may tell, be she doctor or nurse, or neither, knowing that she will touch nothing so that I may not listen, if only I will take what she says as she intends it. In matters of science there can be no room for apprehension of this kind. The movements of the heavenly bodies can be no more abstractly considered than the functions of the spinal cord. Both are departments of knowledge, and both are open to both sexes. Yet astronomy and physiology, and every other branch of science, too, may be perverted; but it takes the superior natural powers of man to pervert them in this way.

In thus declining to share in any attempt to interfere with the prerogative of woman to blush for herself upon occasion, I do not resign the right of man to blush for his own sex. I protest against the introduction to this discussion of the element implied in the question I have already quoted.—I am, &c.

February 4th, 1878. J. ASHBURTON THOMPSON, Member.

## CHARGES FOR COMPOUND VISITS.

SIR,—I should be glad if any of your readers could inform me as to what would be a fair amount to charge in the circumstances I shall describe. The proprietors of an educational and boarding establishment brought his boarders to a house here for summer quarters. An epidemic of diphtheritic sore-throat broke out among them, and was confined to their house alone. Five children were attacked, all of whom recovered. The attendance lasted for three weeks. There were sixteen visits in all; but on most of these there were from two to four patients to see, and, as a general rule, the best part of an hour was taken up at each visit. Of course, I did not, and never do, supply medicine.

If you can give me an idea of what would be a fair charge in such a case in an early number of the JOURNAL, I should be much obliged.—I am, yours truly,

February 1878. M.D.

P.S.—I think there were six patients altogether; but as it happened last autumn, I cannot be positive.

## A NEW(?) EDITION.

SIR,—Anxious to procure the last work on diseases of the throat, I have lately purchased the so-called second edition of *Lessons in Laryngology* by Dr. Prosser James, which I have seen advertised. To my astonishment, I find that it differs in no respect from the first edition of 1873, except that there is a new titlepage, with the words "Second Edition" imprinted thereon, and a few lines added to the blank portion of preface. In point of fact, the second edition is only a new titlepage to the unbound and unsold copies of the first edition. As a simple comparison of the first and second editions will satisfy you as to the correctness of my statement, I do not think it necessary to do more than sign myself

February 25th, 1878.

A STUDENT OF CHARING CROSS.

## HOW TO EMBALM A BODY.

SIR,—“Armenia” asks, in the JOURNAL of February 2nd, “How to embalm a body?” He will find full particulars in a paper by Dr. Richardson in one of the numbers of the *Medical Times and Gazette* about three or four years ago.—I am, &c., L.R.C.P.

PROFESSOR TEBALDI (Padua).—The work of A. Monson, on the *Physiognomy of Mental Disease*, is a treatise on the expression and physiognomy of lunatics, with portraits.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Post; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Keshmerham and Masbro' Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Derbyshire Courier; The Auckland Times and Herald; The Auckland Chronicle; The Western Mercury; The Daily Courier; The Lincoln Gazette; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Richmond and Ripon Chronicle; The Cambridge Independent; The Madras Mail; The Ashton Reporter; Saunders' News Letter; The Western Mail; The Bath Chronicle; The Bolton Chronicle; The Lincolnshire Chronicle; The Chippenham Chronicle; The Crewe Guardian; The West Sussex Gazette; The High Peak News; The Cardiff Times; &c.

\* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

## BOOKS, ETC., RECEIVED.

Anatomy: Descriptive and Surgical. By Henry Gray, F.R.C.S. Eighth Edition. By T. Holmes, M.A. Cantab. London: Longman, Green, and Co. 1877.  
Text-Book of Science: Treatise on Photography. By W. de Wiveleslie Abney F.R.S. London: Longman, Green, and Co. 1877.

# ABSTRACT OF CLINICAL LECTURE

## A CASE OF ACUTE ATROPHY OF THE LIVER.

By R. SHINGLETON SMITH, M.D., Lond., B.Sc., M.R.C.P.,  
Physician to the Bristol Royal Infirmary, and Lecturer on  
Physiology in the Medical School.

J. G., AGED 42, married, a labourer, was admitted to the Bristol Royal Infirmary on August 29th, 1876. He stated that he was quite well till a month ago, when he became sick on two or three occasions, and he noticed that his urine had become of a high colour; he felt a little pain in the bowels at times, but it was never severe. These symptoms continued for a fortnight, and then he first noticed that his skin was getting yellow. His usual weight had been fourteen and a half stone, but he had become much thinner during the last month. His general health had been good; he was never laid up from illness, and never had jaundice before. He said that he had not been intemperate, but admitted that he had taken beer freely during the summer, and had been frequently drunk, as often as once a week. He was formerly in the 13th Light Dragoons, and served through the Crimean campaign; since then, he had been to New Zealand, but had never resided in any tropical country.

*Condition on Admission.*—He was a finely built robust man, well nourished, but found to weigh on August 7th only eleven stone seven pounds. The skin and conjunctiva were very deeply jaundiced. Urine was abundant in quantity, 116 ounces on September 1st, of specific gravity 1012, of a very deep brown colour, with sediment of lithates; no albumen. He did not complain of pain, nor had there been sickness of late. He felt weaker than usual, and was becoming rapidly thinner. He could eat well, but the tongue was furred. The bowels acted regularly, but the evacuations were of a light grey colour. Pulse 52, regular. The sounds of the heart and lung were normal. On examining the abdomen, it was found that the amount of liver-dulness had considerably diminished, there being only just two fingers' width of percussion-dulness in the line of the right nipple, the lower margin of dulness being nearly three inches above the margin of the ribs, the upper line of dulness being about two inches below the nipple. The liver could not be felt by palpation. There was no tenderness on pressure. There was no evidence of splenic abnormality. His temperature on September 1st was 97.6 deg.; and the temperature varied night and morning as follows.

Morning.			Evening.		
September 2	97.2	98.4	September 12	97.6	97.6
" 3	97.4	98.6	" 13	97.2	97.6
" 4	98	99	" 14	97	97.8
" 5	98.6	98.8	" 15	97	97.4
" 6	98	98.4	" 16	97	96.8
" 7	98.2	98.8	" 17	97.4	96.8
" 8	98	98.6	" 18	96.6	97.2
" 9	97.8	98.2	" 19	96.6	97.6
" 10	98	97.8	" 20	97	96.6
" 11	97.6	97.2			

There was no ascites, no enlargement of the abdominal veins, no history of piles, nor of any discharge of blood from the intestinal canal. The pulse varied slightly from day to day. On September 1st, it was 48; and on this day, a trace of albumen was detected in the urine. On September 2nd, the pulse was 64; on the 4th, 48; on the 5th, 52; on the 6th, 56; on the 7th, 64; on the 8th, 72. On this day, it was noticed that the urine had been slightly paler in colour and did not assume so deep a tint on adding nitric acid; the fæces were also found to contain a little bile. On the 9th, the pulse was 76; 122 ounces of urine were passed. On the 11th, the pulse was again down to 56; and on the 12th, the pulse was 60; urine, 130 ounces, specific gravity 1013, darker in colour than before. On the 13th, the pulse was 76; the urine 104 ounces, specific gravity 1013, the colour again lighter, and some bile was again observed in the fecal evacuation. On the 16th, the pulse was 92; urine, 130 ounces, specific gravity 1012, paler; and again there was a little bile in the fæces. He had been slightly delirious in the night. Hitherto his mental condition had been that of health; he had been able to get up, and took food well; but, nevertheless, he emaciated very rapidly. On the 18th, the pulse was again 52; the urine was brighter in colour, but became very deeply coloured

by nitric acid. The pulse was noticed to be irregular and variable in volume. The urine and breath had a peculiar feculent odour. He had been again delirious in the night, and had vomited frequently since the morning before. On the 19th, he was apathetic, but conscious, with no delirium. The vomiting had been allayed by a hypodermic injection of morphia (one-sixth of a grain) and atropine (one-sixtieth of a grain). There had been no vomiting since the injection. The pulse varied from 72 to 96. On the 20th, he became totally unconscious at 3 A.M., and remained so during the day, moaning almost incessantly. The pulse was 120, small and weak. An enema was administered, and some yellow coloured motion came away. There was no return of consciousness, and he died at 3 A.M. on the 21st.

*POST MORTEM EXAMINATION*, thirty-four hours after death.—The body was fairly nourished, and was that of a very muscular, robust, well built man. The skin was everywhere deeply jaundiced. A scar was visible on the left knee from a bullet-wound received at Balaclava. On opening the abdomen, the liver was not seen, the intestine coming into contact with the diaphragm. The liver, pancreas, and duodenum were removed together, and the common duct, opened above, was traced down to the duodenum; no obstruction was found, a probe passed easily into the intestine; the lining membrane of the duct presented the normal appearance, and the orifice in the duodenum was free. There was a condition of catarrhal-like congestion of the mucous membrane of the stomach and duodenum, and this was particularly marked around the orifice of the duct; the mucous membrane was distinctly stained with bile. The gall-bladder was small, containing only about an ounce of dark-coloured, viscid, inspissated bile; no calculi were present. The liver was small, of about one-half the normal size, not altered in shape, fairly smooth on the surface, of a bright yellow colour. It was firm in consistence, not tearing easily, not easily penetrated by the finger. No marked flattening of the organ was present; nevertheless, it was flaccid, although tough and somewhat leathery. The yellow colour was not uniform either on surface or on section; distinct lobules could be seen of a brilliant yellow colour, but these were separated by a pale interlobular tissue. The pancreas was of a very dark colour externally from bile-staining, but its substance presented nothing abnormal internally. The spleen was small, of u-sual consistence. A white patch on the surface, about three-fourths of an inch in diameter, was found to be due to fibrous thickening of the capsule. The kidneys were of a deep brown colour, and congested, but their texture appeared to be healthy. The heart, lungs, and brain presented no marked abnormality.

*Examination for Leucine.*—The patient's urine was on several occasions examined by Dr. J. Greig Smith, who found that, on concentrating the urine to the consistence of a thick syrup, a whitish-flaky substance collected on the surface of the fluid, consisting of bodies which were found to be globular in form; some of them had concentric markings and some of them assumed a crystalline appearance, with lines radiating from the centre. They were freely soluble in water and in spirit. They were very friable, the pressure of the cover-glass being sufficient to destroy the shape of many of them. Several slides of the leucine-globules were mounted in glycerine jelly; but, in the course of a few days, they changed their character almost completely, and were found to have become much more crystalline than before. A more or less irregular globular outline, looking very much like an oil-globule, the centre of the globule being occupied by a number of fine acicular crystals (tyrosine), which traversed the globules from side to side and did not appear to radiate from the centre, was the condition now prevailing; in some few of the masses, the acicular crystals were seen to project beyond the edges of the globular body.

*Leucine* was also found in abundance in the liver after death. A small piece of the liver was immersed in methylated spirit, and in two or three days the spirit had assumed a brilliant yellow colour. On filtration, a perfectly clear yellowish fluid was obtained, which after a few minutes' exposure to the air became turbid; this turbidity was due to the precipitation in great abundance of yellowish globular masses of leucine, which were found to be insoluble in ether and in water, and only sparingly soluble in alcohol. When mixed with water, they floated just beneath the surface and would not subside.

*Microscopic Examination of the Liver.*—Fresh sections, made with Valentin's knife and examined in glycerine, showed the following morbid conditions:

1. Considerable hypertrophy of the fibrous stroma of the organ. The lobules were distinctly marked in consequence of the development of a considerable quantity of interlobular fibrocellular tissue. The whole of the lobules, too, were pervaded by a distinct inter-cellular network of fibrous tissue prolonged from the interlobular growth.
2. An atrophic condition of many of the lobules, their diameter being considerably reduced.

3. Almost complete disorganisation of the liver-cells. Yellowish brown masses, resembling the cells, could be seen here and there occupying the position of the cells; but, under the higher powers, were resolved into granular masses of *débris*.

4. The whole tissues of the organ were pervaded by small globules looking like oil, but many of them were found with higher powers to be leucine-globules.

5. The yellow colouring matter was seen to have crystallised in small rhomboidal masses, looking like minute crystals of hæmatoidine. Many of the leucine-globules obtained from the urine during life, and many of those found in sections of the liver, had lost their original yellow colour, but contained instead one or more minute crystals of hæmatoidine.

After hardening in chromic acid, these appearances were considerably modified.

1. The interlobular stroma resolved itself into a small-celled growth resembling adenoma, and the lobules were infiltrated with cells of a similar character.

2. The liver-cells were much more distinct than before, and now presented the aspect of a cohering mass of brown granules, preserving the shape of the original cells, excepting that they appeared to be smaller than the healthy liver-cell. No nucleus and no distinct oil-globules were visible.

3. The leucine-globules and the minute crystals of hæmatoidine were not present.

It will be observed that the effect of the chromic acid was to reduce the appearance to a condition resembling the early stage of *cirrhosis of the liver*; but the fact that the liver was reduced to one-half its normal size without becoming granular, and without giving rise to any indication of portal obstruction, clearly indicates that the condition was not one of simple cirrhosis. Then, again, the appearance of the hepatic cells, or rather their *débris*, when examined in fresh section not acted on by chromic acid, was characteristic of acute yellow atrophy. Indeed, such an amount of cell-disintegration does not always exist in typical cases of the disease. In one case, examined by M. Robin, quoted by Cornil and Ranvier, it was found that "les cellules, bien que granuleuses, infiltrées de pigment et en partie atrophiques, n'étaient pas détruites. On pouvait les voir en place dans toute l'étendue de l'ilot". It is added that "le tissu conjonctif périlobulaire n'était ni épaissi ni enflammé".

The appearances of acute yellow atrophy are summed up by MM. Cornil and Ranvier as follows. "Telle est la série des lésions des cellules hépatiques, commençant par l'état trouble et l'infiltration biliaire et aboutissant à la fragmentation et en ramollissement destructifs de ces éléments. En même temps le tissu conjonctif périphérique aux ilots et même celui qui accompagne les vaisseaux capillaires des ilots, subit, d'après la majorité des auteurs d'anatomie pathologique, une infiltration albumino-fibrineuse, et on y trouverait des cellules lymphatiques épanchées." The authors themselves have never seen such thickening or inflammation of the perilobular connective tissue; but M. Winwarter reports a case, fatal in twenty-four hours, in which the condition was marked, and he considers that inflammation of the peripheral connective tissue of the lobule constitutes the initial lesion of the disease in question. The case reported tends to bear out M. Winwarter's opinion, presuming that we had to deal with a simple disease; but it is quite open to us to consider whether the condition, acute atrophy, was not secondary to early cirrhosis. Pathologically, the interlobular condition was indistinguishable from that of cirrhosis; but, clinically, there had been no indication of any interlobular infiltration or of any interstitial cicatrization. The habits of the patient and his history were such that an early stage of cirrhosis would be not improbable; and the peculiarities of the case, which distinguish it from a typical one of acute atrophy of the liver, point to the same supposition. These peculiarities were:

1. The intensity of the jaundice, much more so than is usually observed in acute atrophy.

2. The fact that the hepatic dulness had diminished to one-half when the patient first came under observation, and that no further decrease occurred during the following three weeks.

3. The tardiness in the development of the special symptoms—delirium, vomiting, etc.

4. The duration of the disease. Death took place five weeks after the jaundice was first observed, and seven weeks from the commencement of illness. Frerichs states that, of twenty-eight cases, as many as thirteen died in the first week, and only four lived to the fourth week; but he also states that the stage of premonitory symptoms may be prolonged, that jaundice may supervene after several weeks, and even then may exist in the simple form for a period of eight to fourteen days.

5. The absence of petechiæ, and of the various hæmorrhages which are usually present in the later stages of acute atrophy.

6. The toughening of the liver which was found at the *post mortem* examination, and the consequent absence of flattening of the organ, which is usually so marked a feature of the acute atrophic liver.

On the other hand, the features in the case which decisively characterise the disease as acute atrophy were sufficiently prominent. They were:—1. The marked atrophy without contraction, and portal constriction or granulation; 2. The disintegration of the liver-cells; 3. The presence of leucine, detected in the urine during life, and abundant in the liver after death, and the coexistence with it of crystals of hæmatoidine; 4. The low temperature of the patient and the slowness of the pulse, together with the peculiar variations in the pulse during the last few days of life; 5. The more special symptoms of acute atrophy—vomiting, delirium, and coma—which first presented themselves five days before death.

The coexistence of cirrhosis with acute atrophy is a condition not usually recognised by authors. The case is an interesting one, whatever view we adopt concerning it; whether we consider that it establishes the above connection, or whether we regard the interlobular tissue as one of the features incidental to the changes of acute atrophy. If we adopt the latter hypothesis, the case strongly supports the opinion held by M. Winwarter, that an inflammatory condition of the connective tissue around the lobules forms the initial lesion of the acute atrophic disease.

## THE TREATMENT OF AORTIC ANEURISM.\*

By HENRY SIMPSON, M.D. Lond.,

Physician to the Manchester Royal Infirmary, etc.

HAVING had, during the last two or three years, cases of aneurism almost constantly under my care, I venture to bring before the Section some of the thoughts suggested by clinical observation. Passing over the causation of the disease, and also all historical retrospect as regards treatment, on account of the brief period allotted to a paper, I will proceed at once to the special subject of my remarks.

The two objects aimed at by treatment are the solidification of the contents and the strengthening of the walls of the sac.

As regards the first, we may adopt measures for retarding the arterial flow by rest, position, diet, and medicines; or we may try to produce deposit of fibrin and coagulation by galvano-puncture, compression, etc. I purposely omit deligation and the various expedients of the surgeon in aneurism affecting the vessels of the limbs. As regards the second indication, there is some evidence that art is not wholly without power to modify the condition of the vessel-walls.

It seems to me that Mr. Tufnell has put before the profession abundant evidence of the influence of rest and the recumbent position in retarding the blood-current and so favouring the deposit of films or layers of fibrin on the wall of an aneurismal sac; and it is probable that position and rest, if carefully carried out, may, in a certain number of cases, be sufficient to bring about the cure of aneurism. I have, however, had no experience of this treatment alone, and it will rarely, if ever, happen that it cannot be aided by other measures.

To reap the full benefit of it, we have to do all we can to make the patient comfortable in body and content in mind during a period of three months, or in some cases even longer. Mr. Tufnell's directions as to the best mode of doing this are extremely judicious, and I would recommend everyone about to treat a case of aneurism to read them carefully. The patient's room should, of course, be "light, cheerful, and airy"; and Mr. Tufnell gives minute directions as to the preparation of the bed, the object being to secure a smooth even surface to lie on. It requires a good deal of self-control, and indeed courage, for a man who may feel perfectly well, with the exception possibly of some slight beating he does not quite like, voluntarily to lie down, knowing that he must not raise himself in bed for some months; but, with intelligent patients, who understand the gravity of their condition, little difficulty is usually found. There is, however, a considerable difference in the way in which patients bear the irksome monotony of enforced quiet, and this difference varies according to the temper and temperament of the individual. Your ingenuity may be well employed in devising means for diminishing the tedium of this period. Cheerful but not exciting books should be provided, which, if held by the patient, ought to be light. It is better, however, for friends to read aloud than for the patient himself to read. Cheerful but not exciting conversation

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

is desirable. At the same time, all business anxieties or domestic trouble, and the insignificant but fretting worries which make up a good deal of the unpleasant friction of life, are to be avoided so far as it may be possible. A gentleman who was for some months under my care illustrated the importance of these matters very clearly. He is possessed of large landed property on a part of the coast where a scheme was brought forward to reclaim extensive sands, and I could almost always tell when he had had an interview with lawyers or other people on troublesome business. Emotional excitement will very soon tell on the impulse of an aneurism, and indicate the force of the blood-current distending its cavity.

The judicious use of anodynes will aid in lessening the bad effects of excitement, which, in these times of eager restlessness and arduous struggle, no doubt, plays a more important and more injurious part in illness than in the less ambitious days of our forefathers, when tasks were simpler and wants fewer. The bowels and bladder must be relieved, without raising the patient, by the use of the bed-pan and urinal. With some there is a little trouble as to the bowels, especially at first. The alteration of diet which usually accompanies this treatment, and the loss of exercise, sometimes produce constipation, which, if not speedily overcome, may give great trouble and discomfort. On the whole, I think it is better to give enemata than aperients; but your own judgment will tell you how to deal with any individual case. There is not usually much liability to bed-sores; but, if the skin over any of the bony prominences should threaten the least tenderness, it should be rubbed with brandy or whiskey.

Mr. Tufnell speaks with more confidence as to the effect of position in reducing the pulsation than I should do; for, though it is, I believe, the best means we have, it is one that I have found in some cases almost inoperative. One man, who was under my care for a long period, was so susceptible that I could seldom, if ever, get his pulse down even to the ordinary standard. In this way, the temper and disposition come to be of importance as affecting the circulation, and so influencing the success of treatment. In some cases, the pulse falls readily to 66 or 64; and these, of course, are in a condition much more favourable for the consolidation of the aneurism than where it remains, as in some of my cases, in spite of treatment, as high as or higher than 100.

Next, with regard to the diet; I have been accustomed to recommend a diet almost identical with that which Mr. Tufnell gives, the aim being to reduce the fluid to as small a quantity as the patient can comfortably do with, and so to diminish the quantity of the blood, but, at the same time, to maintain nutrition at a sufficiently high standard. Some patients are comfortable and free from thirst with the quantity of fluid recommended by Mr. Tufnell, *i.e.*, with eight ounces of fluid in the twenty-four hours: two ounces of milk or cocoa at breakfast, four of water or light claret at dinner, and two of milk or cocoa at tea or supper. I have not given the wine, but have often substituted milk for it; nor do I think that, theoretically, it ought to be given. If small quantities only be used, it will perhaps have no bad effect, but is useless, while larger quantities may be mischievous from its effect on the circulation.

With some patients, however, a good deal of discomfort, and even suffering, would have to be endured if this quantity were rigidly enforced; but it is desirable to exceed it as little as possible, and two or four ounces more will meet the requirements of most cases. In a gentleman who had at one time a good deal of sugar in his urine, thirst was a very troublesome symptom, and I was obliged to increase the drink for a time, as he was falling almost into a typhoid condition. Fortunately, the sugar decreased in quantity, and finally disappeared, and, so far as I know, has not returned, as I heard, about a week ago, that he remained in good health. This happy disappearance of so formidable a symptom took place while he was taking salicylic acid.

The amount of solid food can often be kept down to Mr. Tufnell's standard; namely, for breakfast two ounces of bread and butter; for dinner three ounces of cooked meat, with three of potatoes or bread; and for tea or supper two ounces of bread and butter again. If, however, the patient wish more solid food, I should give some more; but, as a rule, a small addition would suffice. It is of importance not to bring it down too low, as our object is by no means to impoverish the blood, but, on the other hand, to maintain it in a healthy condition. I have seen irritability of the heart and a quickened pulse brought on by cutting down the supplies too much, and the heart's action has been quieted by food. It is remarkable, however, that patients will sometimes get comparatively fat on what to many would seem a starvation diet. This was notably the case in a man named Evans, who was for a good while under my care in the Manchester Infirmary with abdominal aneurism, and who left greatly improved in health, and with his aneurism apparently consolidated.

As regards treatment by drugs: anodynes and opiates should be given, when necessary, to relieve pain, allay cough, and procure sleep, in such doses and at such periods as the individual case may require. Your own judgment will be a safer guide than any suggestions of mine; but it seems to me better to give them when needed, and then to omit them, than to let them be taken in a routine fashion, whether required or not. Digitalis is a medicine I have not used much, if at all, in the treatment of aneurism, because, although it might be convenient at times in reducing the frequency of the pulse, the increased force of the cardiac beat would, I think, more than nullify this advantage.

The drug that has attained the greatest popularity of late in this disease is doubtless the iodide of potassium. It seems now almost universally accepted as being beneficial, though as to this there may still be exceptions. One of those sceptical as to its virtues in aneurism was our ever to be lamented friend and associate the late Dr. Sibson. I had some correspondence with him as to a case in which I believe it was very useful, a few months before his death, and the adverse opinion he then gave was subsequently repeated in conversation. He seemed to think that, if it were ever of service, syphilis was concerned in the production of the disease. In the case referred to this could, I think, certainly be excluded; and I should by no means limit its employment to cases where we either know or suspect a syphilitic influence.

Two opinions have obtained with reference to its action: one that it helps to solidify the contents of the sac by increasing the coagulability of the blood, and the other that its influence is in some way exerted on the walls of the vessel. Its latest and warmest advocate, Dr. G. W. Balfour, has brought forward strong testimony as to its beneficial effects, and, from his large experience, any opinion he may have formed of its action is entitled to our greatest respect. He thinks that, in some way or other, its influence is exerted not on the blood, but on the vascular walls; "that relief is obtained by some peculiar action on the fibrous tissue, whereby the walls of the sac are thickened and contracted; while, if coagulation should take place within the sac, it plays but a very secondary and unimportant part, depending for its occurrence solely on the remora of the blood, and is in no respect due to the iodide of potassium". I entirely agree with this view of its action, and am not aware of the existence of any evidence showing that it does in any way cause coagulation of the blood in the aneurism, or directly bring about the deposition of fibrin on the walls of the sac. The only point that suggests itself to my mind is that, if it favour the induration of the sac wall and the production of calcareous plates, a projecting fragment or roughened surface may lead, in some instances, to a minute deposition of fibrin which would serve as a nucleus for further accretion. My experience also leads me to endorse his statements as to the remarkable effect it so often has in relieving the pain accompanying aneurism. Sometimes it produces coryza, but certainly, I think, as seldom in large as in small doses, if not more seldom. How this is I do not pretend to say, nor do I attempt to explain its action in syphilis or rheumatism, though, in all these cases, we may believe that it is chiefly exerted on the fibrous tissue.

When first I began to use iodide of potassium in aneurism, I gave about five grains for a dose, and gradually increased it to twenty or thirty; but, for some time, I have at once put the patient on full doses, as saving time and more quickly producing saturation of the system. Tolerance of the drug is the rule; and, when exceptions occur, the dose may be diminished or its use given up for a day or two, or various combinations may be employed. I frequently give with it small doses of carbonate of ammonia and a vegetable bitter. By some, the administration of the iodide is dreaded from the fear of its depressing effect; but I cannot recall an instance where it has had to be omitted on this account, and have often remarked on the fact that it may be given for long periods, not only without injury, but apparently with benefit to the general health. The assimilation of food and the nutrition of the body go on unimpaired; and one patient, as I mentioned before, contrived to lay on flesh under the somewhat rigid diet recommended by Mr. Tufnell, while he was taking half a drachm of the iodide three times a day.

But, while it gives great and even wonderful relief to the patient, who, in consequence, is apt to think in a few days that he is almost well, and will be so very shortly, I am bound to say that, even with the important auxiliaries of perfect rest in the recumbent position and a carefully regulated diet, some of my cases have not improved as I could wish, and the aneurism has progressed. How far this could be prevented by increasing the dose of iodide I cannot say, and shall be glad to know the experience of the members present. I have seldom, if ever, pushed the dose beyond two scruples thrice a day. It is important, I think, to bear in mind the injurious effect of any im-

poverishment of the blood in keeping up an irritable condition of the heart, and to try to remedy this by giving some mild preparation of iron.

Sometimes I have found, when an aneurism has enlarged rather rapidly and begun to protrude externally, good effects from the application of ice, which has been soothing to the patient, and has apparently had a sedative influence on the vascular system. But, in several instances, more striking benefit has followed the employment of galvano-puncture. He was a bold man who first passed a needle into an aortic aneurism, and we who follow are sometimes apt to forget the sagacity and courage of our pioneers.

I have employed this method in five patients, and, in some of these, have repeated it several times. Two cases have been recently reported in the *BRITISH MEDICAL JOURNAL*: one patient, a man named Butler, is now in the Manchester Infirmary, and I have twice assisted my colleague Dr. Dreschfeld with one of his cases. It has also been used by Mr. Heath in a case of subclavian aneurism under the care of our President Dr. Wilkinson. I ought not to omit another case operated on several years ago by my colleague Dr. Browne, where it was very beneficial. The only instance where any ill-effects have followed was in Bowker's case reported in the *JOURNAL*.

The conclusions at which I have arrived so far, subject of course to correction or modification as experience increases, are briefly as follows. I do not look upon galvano-puncture as the treatment for aneurism generally; it can be used only when the tumour projects on the surface, or when we are sure that it is in contact with the parietes, no viscus intervening. The last condition is one which will very easily allow of its being used in abdominal aneurism.

In aneurisms of the thoracic aorta, it is more likely to be useful when they are sacculated than when fusiform. Sacculations are an important element, as the contents of the sac, being out of the main channel, are comparatively quiet, like the gentle eddy close to the current of a rapid stream, yet are not altogether motionless, and so are in a favourable condition for the deposition of fibrin.

I may remark that the statistics collected by Dr. John Duncan show a better result in external aneurisms than in those of the aorta; but of its use in these cases I have no personal experience. My impression would be that they would be better suited for the ordinary surgical proceedings, such as deligation and the various modes of compression, which are inapplicable, of course, to the cases we have to consider. But, even in those most fit for galvano-puncture, I should abstain from its use until the other means mentioned had been carefully and thoroughly tried, except possibly where the patient could not or would not submit to prolonged rest, or where hæmorrhage seemed imminent. Two objects have been aimed at by this method: the coagulation of the whole contents of the sac, on the one hand, and, on the other, the production of a comparatively small but firm clot, which may serve as a nucleus for the further deposition of fibrin. When two needles connected with the poles of a galvanic battery are introduced into a solution of albumen, it is well known that a large loose clot containing much hydrogen gas in bubbles entangled with it is formed at the negative pole, while at the positive pole the clot is small, firm, and white, which fact lies at the foundation of the electrolytic treatment both of tumours and aneurism. Dr. Poore gives a good summary of the subject in his very useful book on *Electricity in Medicine*. The method I have employed in the treatment of aneurism is briefly as follows. Most frequently I have inserted one, two, or, in some cases, three needles into the aneurism, endeavouring to make sure as to the penetration of the sac, which is pretty clearly indicated by the oscillation of the needles, but not passing them more deeply than from one-fourth to one-half an inch. The object of this is to have the clot formed in contact with, and adherent to, the sac wall, so that, on the withdrawal of the needle, it will not be floating loose in the cavity of the aneurism. These needles I have connected with the positive pole of Foveaux's battery, with few exceptions, while the negative pole has been applied to the walls of the chest by means of a large sponge moistened with salt and water, and moved about if the skin have become reddened. This proceeding was adopted, of course, from the wish to produce a small firm clot on which further deposit might take place. Twice or three times recently, I have introduced two needles and connected one with each pole of the battery, because we are thus most certain of producing electrolysis of the blood. The results, however, have not been so much more favourable or better marked than those following my first procedure, though no bad effects have followed, that, on the whole, I feel disposed to return to it.

The first method would produce a firm though comparatively small clot, highly favourable as a nucleus for further deposit. The second would produce a larger though looser clot, and, in some instances, coagulation of the whole contents of the sac might take place. But,

when a large coagulum has been rapidly formed, it has not always been stable, and pulsation has returned in the sac. This suggests the danger of embolism, though I am not aware of any record of its actual occurrence, unless we consider the peculiar and remarkable case mentioned by Dr. Clifford Allbutt as one of this nature.

It seems to me that the first method is safe, and, so far as my experience goes, it may be called satisfactory, and that there are fair grounds for the hope that it will be more so in the future, as our knowledge of its uses and limitations becomes more exact.

With regard to the second, though Dr. Duncan gives the weight of his great authority to the rapid coagulation of the whole contents of the sac, I should be disposed to use it as a sort of forlorn hope to avert death, if rupture or hæmorrhage were imminently threatened. Great pain has been said to attend galvano-puncture; but such has not been my experience, except on one occasion when Stöhrer's battery with large elements was used, and then only when ten or twelve pairs were in action. This freedom from pain was, no doubt, due in great part to the perfect insulation of the needles where they were in contact with the skin, and also to the employment of a battery consisting of small elements. In all the cases where the positive needle was passed into the aneurism, the point became blackened and sometimes much corroded; but increased firmness and consolidation of the tumour have certainly taken place when the amount of action on the needle has been small.

And this suggests the question whether, in some cases, part of the effect may not have been in some measure due to the needle merely acting as a foreign body. I may say that, in all my cases, the condition of the battery has been tested. The current has been passed through the tumour for a variable period, most frequently for about two hours; and, where pain is not produced, there seems no reason why this should not even be exceeded.

Dr. Duncan gives the dangers of galvano-puncture, as hæmorrhage and inflammation of the sac or its contents; for we may practically exclude embolism. The first is best avoided by using well insulated needles, which we may almost take for granted will be invariably employed. In Riley's case, recorded in the *JOURNAL* of July 14th, death took place from syncope, preceded by slight hæmorrhage; but, in his case, galvano-puncture was used almost as a forlorn hope. Should a similar case occur to me again, I should probably introduce two needles and connect one with each pole of the battery, in the hope of producing rapid coagulation of the whole contents of the sac.

In Bowker's case, recorded in the same *JOURNAL*, though no bad symptoms occurred for a fortnight after the operation, I am disposed to blame the battery—Stöhrer's, with large elements—rather than galvano-puncture itself for the abscess involving the sac and its contents, which led to his death from hæmorrhage. The best mode of avoiding this danger seems to be by using a battery of small elements.

I have had no experience of the ligation of a distal branch of the thoracic aorta as used by Mr. C. Heath, nor of compression of the abdominal aorta, as successfully adopted by Dr. Philipson, and therefore will not discuss them in this paper.

Such is a brief and fragmentary sketch of the principles and practice I have been led to adopt in the treatment of aneurism. They are very simple. Rest in the recumbent position, maintained for a long period and most carefully and thoroughly carried out. This is of importance if benefit be looked for. The avoidance as much as possible of all sources of excitement. The use of suitable anodynes to relieve pain, allay cough, and procure sleep. A careful but sufficiently nutritious diet, with as small a quantity of fluid as the patient can comfortably bear; the exhibition of iodide of potassium in full doses for a long period, and of iron if there be any anæmia. Where these means have been insufficient, I have used galvano-puncture with a sufficient amount of success to justify me in adopting it again in suitable cases.

In all my patients, life has been prolonged and much relief obtained. In four, what we may almost venture to call a cure has been effected, though I should always be cautious in speaking positively as to the cure of a disease where, when things look most promising, a thin film or a portion of clot hidden from view and inaccessible to observation may be all that separates life from death. Three deaths have occurred: two already recorded, and the third where the patient was removed from treatment by the occurrence of violent mania, though even here he only succumbed after many months of apparent health. Other cases are still under treatment with prospects more or less encouraging. I must not burden this paper with cases, but hope shortly to give a brief record of them.

In conclusion, I would venture to hope that my experience, though chequered, is not so dark as to discourage those who have to undertake the treatment of internal aneurism.

## TWO CASES OF ANEURISM OF THE ABDOMINAL AORTA;

ONE CURED BY THE ADMINISTRATION OF IODIDE OF POTASSIUM, THE OTHER BY ARTERIAL COMPRESSION.\*

By G. H. PHILIPSON, M.A., M.D. Cantab, F.R.C.P. Lond.,  
Professor of Medicine in the University of Durham; Physician to the Newcastle-upon-Tyne Infirmary; etc.

DURING the year 1876, two hundred and sixty-seven patients were admitted at the Newcastle-upon-Tyne Infirmary, under my care, of whom one hundred and eighty-three were in-patients and eighty-four were out-patients. Of the whole number, four were suffering from aneurism; one of the arteria inominata, and three of the abdominal aorta. Of the three cases of abdominal aneurism, I propose giving the particulars of two; the third patient was only eight days in the hospital. For comparison, therefore, this case is of little value, and, consequently, will not be recounted.

CASE I.—Robert R., aged 26, labourer, married, living at Crook, in the county of Durham, was admitted on June 8th, 1876. He stated that he had been unable to follow his employment for nine weeks, in consequence of pain in the back, which pain was severe and passed round the abdomen to the region of the umbilicus, where, at times, it was excruciating. Upon carefully examining the abdomen, a faint pulsatile prominence was seen near the umbilicus, at which situation, upon placing the hand flat, yet firmly, a pulsation was felt, more to the left of the umbilicus, which pulsation was expansile in character. At the spot where the pulsation existed, there was dulness upon percussion, and a blowing systolic murmur was heard. Upon auscultating the left vertebral groove, a distinct systolic murmur was heard. The respiration, over the whole of the chest, was of natural frequency and character. The heart-sounds were normal. He was of sanguineous temperament, and in good nutrition. He had no knowledge of having sustained a fall, blow, or strain, and denied ever having suffered from syphilis. The case was regarded as one of aneurism from the following physical signs: the pulsation visible, perceptible, and expansile; the dulness upon percussion; and the murmur heard at the site of the pulsation in the abdomen and in the left vertebral groove. And further, it was inferred that the aneurism was of the abdominal aorta, from the situation of the pulsation, and of the variety, lateral, sacculated, and not peripheric, dilating, from the pulsation and the dulness being to the left of the umbilicus.

The patient was selected for the clinical medical examination for degrees in Medicine of the University of Durham. The diagnosis was confirmed by my colleague Dr. Arnison.

The patient was ordered to maintain the horizontal position in bed, to take ten grains of the iodide of potassium in one ounce of water, three times each day, and to have the ordinary meat diet.

June 15th. Of his own accord, he mentioned that he was sensible of a beating in his abdomen, and that he had experienced a beating for fully six weeks previous to his admission. The iodide of potassium was increased to fifteen grains.

June 24th. The pulsation was decidedly less forcible. The iodide was increased to twenty grains.

July 1st. He still complained of pain in the back and round the abdomen. The pulsation was less expansile. No murmur was heard. The iodide was increased to twenty-five grains.

July 8th. There were still paroxysms of pain, accompanied with difficulty in micturition. The iodide was increased to thirty grains.

July 15th. The pain was less severe, more continuous. Upon careful palpation, scarcely any pulsation was felt. The iodide was increased to thirty-five grains.

July 22nd. There was now very little pain. The iodide was increased to forty grains.

July 29th. No pulsation was visible or perceptible; no murmur.

August 12th. As no pulsation had returned, or murmur was to be heard, the patient was permitted to leave his bed for a portion of the day. The iodide of potassium was continued in doses of forty grains.

The condition of immunity from pulsation and from murmur continued, and he left the hospital on October 7th, 1876, to resume his occupation. He was instructed to present himself after an interval of two months, which he did on December 20th, 1876, when after very careful examination, no pulsation was detected, nor was any murmur heard. He expressed himself as feeling well, free from pain, and had been able to continue at work as a general labourer.

CASE II.—John H., aged 25, married, a shingler at the Ironworks,

living at Stockton-on-Tees, was sent to me by my friend Dr. R. W. Foss of that town on October 28th, 1876, as a patient suffering from abdominal aneurism, to be placed under treatment in the Newcastle Infirmary. After careful examination, I coincided with Dr. Foss in the opinion expressed, and gave instructions for the patient to be admitted into the Infirmary.

On October 30th, my colleague Dr. Embleton, the Senior Physician to the Newcastle Infirmary, being at that time engaged in delivering the clinical medical lectures, selected this patient for examination and consideration by the class of students in medicine, as a case exemplary of abdominal aneurism. The patient stated that for four months he had been unable to follow his employment, on account of pain in the back, more especially in the lumbar region, and at times round the lower part of the abdomen and the inner surface of the thighs. He described the pain as "burning" and "plunging". For five weeks, he had been sensible of a beating in his abdomen near the umbilicus. On the abdomen being uncovered, it was noted that there was a prominence, which pulsated. The site of the pulsation was to the right of the umbilicus, and for about one inch above the umbilical line. The pulsating surface was smooth to the eye. When the hand was placed on the prominence, a tumour was distinctly felt, equal to an ordinary orange in size, which pulsated out of proportion with the moving mass. On the anterior prominence, the hand received a single systolic impulse of considerable force. The hands placed on each side of the mass received an impulse laterally as well as anteriorly, which impulse was distinctly expansile. The chief pulsation was to the right of the spine. The tumour was immovable, and was dull upon percussion. A slight thrill was perceptible, which was systolic; a second impulsive or shaking action, diastolic in time, was also felt. Upon auscultation, a systolic murmur was heard. Upon applying pressure to the abdominal aorta, between the tumour and the ensiform cartilage, the pulsation in the tumour and in the femoral arteries was arrested. Upon being interrogated respecting syphilis, he admitted that, five years ago, he had suffered from gonorrhœa, and from a bubo which had suppurated; but had not suffered subsequently from sore-throat or eruption. In his occupation, he had been exposed to great heat, and had been accustomed to drink largely of ale, some days taking as much as ten pints, and, at times, spirit in addition. He was fair in his complexion, and of a spare build. The case was regarded as one of aneurism of the abdominal aorta, situated just above the bifurcation, and in variety as lateral, sacculated, and enlarging to the right. He was ordered to remain quiescent in bed, in the recumbent position, to take ten grains of the iodide of potassium in one ounce of infusion of quassia three times each day, and to have the ordinary meat diet.

November 8th. He complained of having a troublesome cough. Upon careful examination of the chest, sonorous rhonchi were heard on both sides, but nothing more abnormal. He was ordered the customary cough-mixture each night.

November 11th. He stated that his cough was much relieved, but that the pain was still severe in the back and loins. Upon inspection, no pulsation was recognised. Upon auscultation, no murmur was heard. Upon palpation, the pulsation was less forcible, and the tumour was smaller. The iodide was increased to twenty grains.

November 18th. The pain in the back had been less severe. The pulsation was more evident to the eye, and was more perceptible to the hand. It was elicited that the patient, against the instructions given, had been leaving his bed each day. Quiescence was again strictly enjoined. The iodide was increased to thirty grains.

November 25th. The pulsation was very slight. The iodide was increased to forty grains.

November 29th. A pustular eruption had appeared on the forehead and chest.

December 1st. The pulsation had continued very slight. After consulting with Dr. Embleton, it was determined to employ arterial compression on the cardiac side of the aneurism.

December 2nd. The patient being uninfluenced by chloroform or other anæsthetic, Lister's abdominal tourniquet was applied to the abdominal aorta, four inches above the umbilicus, by Mr. G. E. Williamson, senior house-surgeon, who was aided by Mr. J. D. Dixon, junior house-surgeon; Mr. G. B. Craig, clinical clerk; and Mr. A. M. Goyder, clinical clerk. I readily avail myself of this opportunity of acknowledging the kind and valuable assistance of these gentlemen, and of expressing my appreciation of their willingness to carry out my wishes. The compressing pad was firmly screwed down, but the patient complained of such extreme pain, that the administration of an anæsthetic was necessitated. He was at once placed fully under the influence of chloroform, and the compressing pad was screwed down until pulsation was arrested in the aneurism and in both

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

femoral arteries. The pressure was continued for half an hour, and upon being removed, the pulsation in the aneurism immediately returned.

December 5th. The patient was placed fully under the influence of chloroform, and the pressure was applied in the same manner as before stated, and was continued for three-quarters of an hour; and upon its removal, the pulsation returned as before.

December 8th. When the patient was fully anaesthetised by chloroform, the pressure was applied in the same manner as on the two preceding occasions; and while it was being continued, the radial pulses became so feeble that it was deemed expedient to discontinue the administration of chloroform, and to maintain the anaesthesia by ether, under which the circulation revived. The pressure was maintained for one hour and a half (from 8.30 P.M. to 10 P.M.), and upon its removal, the pulsation in the aneurism returned as before.

At 1 A.M., on December 9th, the clinical clerk was hastily summoned, and found the patient restless, complaining of pain in the abdomen, which was general and not fixed to one spot, and passing bloody mucus from the bowels. A hypodermic injection of morphia (one-third of a grain) was administered, and a draught containing thirty minims of the tincture of the perchloride of iron in water was given internally.

December 9th, 11 A.M. The patient was still restless, passing bloody mucus from the bowels, vomiting and retching continuously, and complaining of general pain in the abdomen. He had passed urine, which was of specific gravity 1020, and contained no albumen. Upon very careful examination of the aneurismal tumour, the pulsation was considered to be more marked than it had been previously to the application of the pressure. He was ordered to take milk with potash-water, to have a morphia suppository (one-third of a grain) administered in the evening, and to continue the iron draught every four hours.

December 10th. Mr. Williamson, at his morning visit, observed that the aneurismal tumour felt harder, but was still pulsating; and at his evening visit, found that there was no pulsation in the tumour or in the femoral arteries. The patient still complained of pain and uneasiness in the abdomen, and was occasionally troubled with vomiting, and voided bloody mucus *per anum*.

December 11th and 12th. The patient's condition had remained unchanged, excepting that the temperature of the lower extremities had been perceptibly diminished, and had required the application of additional blankets and the hot-water tin for the maintenance of warmth.

December 13th. The vomiting had ceased and the passage of bloody mucus had stopped. The radial pulse was 60 and steady. At the site of the former pulsation, in the abdomen, there was a hard tumour, of about the size of a cricket-ball. There was no pulsation visible or perceptible to the hand, and no murmur was heard. Upon careful palpation in the line of the abdominal aorta, on the cardiac side of the aneurism, no pulsation was discernible. At the ensiform cartilage the heart-sounds were distinctly heard; but, about one inch and a half below the ensiform cartilage, no sound was heard, and no sound was recognised in the line of the abdominal aorta. The heart-sounds were normal both at the base and the apex. There was no pulsation in either femoral arteries. There had been no suppression of urine, and the urine in character had been normal, of specific gravity 1020, and had contained no albumen. There had been no complaint of headache or of change of vision, or alteration of any of the special senses.

Perfect repose was enjoined, and he was ordered to continue the milk and potash-water.

December 16th. The patient had continued easy. The radial pulse was 72, and regular. The bowels have acted naturally, and the evacuation was free from blood. The tumour was decidedly smaller and was less hard.

December 20th. In both groins some pulsation was noted, weak but distinct, and not in the situation of the femoral arteries. Upon deep pressure, a cord could be felt on each side, which was regarded as the femoral arteries. The cord did not pulsate. In the posterior-tibial arteries slight pulsation was perceptible.

December 23rd. The tumour had considerably diminished in size. The patient was permitted to be raised in bed upon the rest, and was allowed the ordinary meat diet.

December 27th. The temperature of the lower extremities had increased, so that the hot-water tin had been dispensed with.

December 30th. At the site of the aneurism, there was not anything to be seen, felt, or heard. The condition of the abdominal aorta remained as last stated, and there was no pulsation in the femoral arteries.

January 10th, 1877. For the last fortnight the patient had been walking about in the ward. When interrogated, he answered that he was quite free from pain or other discomfort, and that "he felt as well as

he had ever done in his life". He expressed himself as wishful to return to his home; but when informed that it was important for him not to resume his previous occupation, he readily consented to remain.

At the monthly meeting of the Northumberland and Durham Medical Society, held on Thursday, January 11th, 1877, the patient was introduced, the site of the aneurism was pointed out, also the position where the compression had been applied; and it was demonstrated that there was no pulsation in the aneurism, in the abdominal aorta, or in the femoral arteries.

January 31st, 1877. The patient was placed under the influence of ether, and a careful examination was instituted. At the site of the aneurism, no tumour was distinguished. Some arterial pulsation was felt to the left of the umbilicus, which was regarded as the enlarged colica sinistra branch of the inferior mesenteric artery. In all respects the condition was satisfactory.

On February 1st, 1877, the patient left the Infirmary to return to his home.

As Case No. 11 undoubtedly was cured by the compression of the abdominal aorta, it will be desirable that reference should be made to the first recorded case of the cure of an aneurism of the abdominal aorta by pressure, which case occurred in the practice of Dr. William Murray of Newcastle-upon-Tyne, in the year 1864. The interest and value of the case are enhanced by the importance of its verification on necropsy.

The following outline of the case is taken from Mr. Timothy Holmes's Lectures on the Surgical Treatment of Aneurism, delivered before the Royal College of Surgeons of England, in the year 1872, and reported in the *Lancet*. "The patient was a spare young man, aged 26. The tumour was situated so high that the aorta was believed to be felt below it, pulsating naturally. It extended up to within three inches of the margins of the left ribs. Still there was room between the umbilicus and the ribs for the pad of the tourniquet, which was applied on the first occasion (April 16th, 1864) for two hours, and on the second occasion (April 19th, 1864) for five hours. On neither occasion was the circulation completely and permanently suspended, except for the last hour of the last and successful attempt. At the end of the second application of pressure, 'very slight pulsation was felt, and hopes were entertained that some advantage had been gained'; but, to the operator's surprise, the pulsation in the tumour altogether disappeared that evening, and the cure was complete and permanent. The man remained well, gaining his livelihood by a 'variety of labouring occupations', till the year 1870, when, having resumed his original occupation of a pavior, he again presented symptoms of aneurism of a higher part of the abdominal aorta, and died on July 1st, 1870, from rupture of this aneurism, which affected the vessel near the coeliac axis. The preparation which was removed from the body showed the first aneurism perfectly consolidated, and seated in the abdominal aorta, extending from close above its bifurcation to about an inch above the origin of the inferior mesenteric artery. The aorta was occluded above the aneurism and its walls atrophied. The aneurism itself was also converted into a fibrous mass. The aorta was largely dilated up to the new aneurism, which had become 'diffuse' before death. As regards the collateral circulation, outside the abdomen, 'it was carried on between the internal mammary and the deep epigastric; between the hepatic artery and a branch of the epigastric; between the intercostals and the deep epigastric; between the intercostals and the superficial epigastric; and between the lower intercostals with the superficial circumflex iliac'. Within the abdomen, 'the circulation was carried on between the colica media of the superior mesenteric artery and the colica sinistra branch of the inferior mesenteric, including its sigmoid and hæmorrhoidal branches; between the upper lumbar arteries and the ilio-lumbar; and between the lower lumbar arteries and the circumflex ilii'. The superior mesenteric artery was dilated to nearly the size of the aorta itself, and the trunk of the inferior mesenteric was so much dwindled that its trunk was hardly half the size of its branches, in consequence of its supply of blood being cut off by the consolidation of the aneurism from which it springs."

REMARKS.—In contrasting the two cases that have been recounted with each other, and Case No. 11 with Dr. Murray's case, it would appear that the establishment of the diagnosis of aneurism, the correctness of the situation fixed upon of the aneurismal tumour, the etiology, the anatomical or specific character of the aneurismal sac, the treatment that was employed, the changes consequent upon the treatment, and the deductions inferable from the treatment, are the points for critical disquisition.

Diagnosis.—In both cases there was a tumour, which was immovable, which pulsated to the eye and to the hand, which was dull upon percussion, and upon auscultation of which a murmur was heard. Now,

such physical signs, when in association, are evidence of aneurism, and of no other kind of tumour, let it be glandular, cancerous, hydatid or other, or of psoas or iliac abscess.

*Situation of the Aneurism.*—In both, it was looked upon as of the abdominal aorta, near its bifurcation. The position and the immobility of the pulsating tumour, together with the neuralgic pains in the spine, pointed to the correctness of the supposition; while the fact that the cure of the aneurism, in Case No. II, was accompanied by the disappearance of the pulse in the femoral arteries, rendered the possibility of the aneurism being situated in the inferior mesenteric artery, or in one of its branches, as highly improbable.

*Etiology.*—Both patients were under thirty years of age. The history of previous syphilis in the second was clear. The supposition, therefore, that in both the lesion of the arterial coats was inflammatory in nature, and not atheromatous, was rendered very certain. If it be true that, in this lesion, an inflammatory process commences just external to the lining membrane, leading to a deposition of lymph there, producing elevation of the internal surface, and, as a consequence of the pressure and of the interruption of the nutrient supply, atrophy and erosion of the endarterial membrane, it may readily be understood how easily the already thinned arterial wall will dilate, and become in time converted into a lateral sacculated aneurism.

*Anatomical or Specific Character of the Aneurism.*—In both, it was observed that the aneurism was of the lateral sacculated variety. In the first case, the sac was enlarging to the left; in the second, to the right. Whilst coagulation of the blood within the aneurism is scarcely obtainable in the peripheric dilating aneurism, in the lateral sacculated variety there is a natural tendency to such coagulation, and coagulation does actually promote anatomical cure. Hence, it would seem that the clinical distinction of these two great varieties of aneurism is not mere scholastic refinement, but of practical importance. For this reason, therefore, is the value of estimating the physical condition of the aneurism; for upon such determination is the treatment to be decided upon.

In the treatment, whether constitutional or mechanical, the principle was recognised that it is necessary for the circulation to be enfeebled or impeded, in order that the aneurismal sac may become filled with the constituents of the blood, and in process of time rendered impervious; the term constitutional treatment being regarded to include the dietetic, medicinal, and postural requirements. In the first case, the object was gained by constitutional treatment alone; in the second, by mechanical treatment, after the constitutional treatment had been unprofitable. The effect, then, of the administration of the iodide of potassium, in association with the rest and the regulated diet, in the first case, may be conjectured to have been the gradual filling, with the constituents of the blood, and the subsequent shrinking of the aneurismal sac, but without obliteration of the aorta, on the cardiac side of the aneurism, the circulation in the arteries on the distal side of the aneurism continuing uninterrupted. In the mechanical treatment, that by the application of pressure, more than this is effected; for it may justly be assumed that the current of the blood along the aorta, and thence into the aneurism, is either wholly or in a great measure arrested. This temporary condition of the aorta and of the aneurism being the same, or nearly similar, to that which arises when a ligature is applied to a large artery on the cardiac side of an aneurism, namely, upon the drawing tight of the ligature, there would be a cessation of the pulsation and of the murmur in the aneurismal tumour, which would at the same time subside, becoming partially emptied of blood. Though the direct flow of blood is arrested by the ligature, after a varying interval of time, blood will enter the aneurismal sac by the interosculating circulation; and it is from this blood that the sac becomes filled, it is supposed, by fibrin, deposited in stratified layers, as in spontaneous cure of the disease. So far, therefore, the mechanical treatment of aneurism by arterial compression, and that by the application of a ligature on the cardiac side of the aneurism, may be compared, and may be regarded as analogous; but, when the compression is removed and the blood again circulates, the condition is very different—in that, where the compression has been employed, the blood circulates directly, passing to the aneurismal sac in its usual channel; but where a ligature has been applied, the blood comes indirectly to the aneurismal sac, passing in a circuitous route. The question presents itself: is this difference such as to determine the deposit of the constituents of the blood, either in laminated fibrin or in coagulum? The interval of time that elapsed between the compression and the consolidation would be in favour of laminated fibrin being first deposited, and subsequently that a coagulum was superadded, filling the aneurismal sac and blocking the aorta. This is the explanation that is offered. The difference of time in Case No. II, in Dr. Murray's case, and in others, for the process to be accomplished, possibly was dependent upon constitutional differences,

more especially upon a difference in the quality and plasticity of the blood.

If it be admitted that the supposition is the correct one: that the filling up of the aneurismal sac is by stratified fibrin, and finally by coagulation of blood, it is unnecessary to apply pressure to wholly interrupt the circulation; but rather moderate compression only is necessary to lower the force of the circulation, and the mechanical treatment should be in accordance with the constitutional treatment.

The channel through which the blood was carried, after the cessation of the circulation in the abdominal aorta, in Case No. II, for the present is visionary; but, from the similarity of the position of the aneurism to that in Dr. Murray's case, which was disclosed on necropsy, and which it was deemed expedient to give when the case was referred to, it may be presumed that the circulation was similarly carried on.

The bloody mucus that was passed *per anum* was regarded as the result of the congestion of the intestinal vessels, following upon the pressure—not the consequence of rupture of the vessels produced by the compressing pad; for, if such had been the condition, blood, either liquid or in the condition of coagulum, would have been voided.

The conclusion deducible from this consideration is, that aneurismal tumours of the lower portion of the abdominal aorta may be successfully treated by arterial compression on the cardiac side of the aneurism; but that this method is a dangerous one, and should not be employed until the constitutional treatment has failed; and that, if arterial compression be employed, it should be moderate and prolonged, rather than complete and of short duration.

## A CASE OF CONGENITAL CYANOSIS, IN WHICH A PATENT FORAMEN OVALE WAS ASSO- CIATED WITH A PRESYSTOLIC BASIC MURMUR.

By GEORGE JOHNSON, M.D., F.R.S.,

Professor of Clinical Medicine. Senior Physician to King's College Hospital.

ON June 1st, 1870, I had, through the kindness of my friend Mr. Charles Hood, the opportunity of examining an inmate of the British Home for Incurables, who from his birth had been cyanosed. I copy *verbatim* the notes which I made on the day of the examination.

"Henry Burgess, aged 27, has been blue from birth; has spat blood; legs cedematous and purple; thumbs and fingers clubbed; pulse feeble, rather small. A bellows-sound over base, alternating with the impulse, rather presystolic than diastolic. The probable cause is a current of blood from the stronger left to the weaker right auricle through the open foramen ovale during the auricular systole. The blueness, the hæmoptysis, and the cedema of legs, are consequences of overfulness of veins, the result of arterial blood going from the left to the right side. He often has headache and giddiness. The normal second sound (valvular click) scarcely audible."

I saw the patient only on that one occasion; and I heard no more of him until the 23rd of last November, when I received a note from Dr. Fairfield, the Medical Officer of the British Home for Incurables, informing me of the man's death, and inviting me to attend the inspection of the body on the following day. Unfortunately, I was unable to attend; but Dr. Fairfield did me the favour to send me the following "Notes of the *post mortem* appearances. Henry Burgess, aged 35. Cyanosis. November 24th, 1877. Lungs healthy. Liver and spleen much enlarged. Heart of an extraordinary size, with open foramen ovale about as large as a five-shilling piece. The hypertrophy general, but especially the right ventricle. The walls of great firmness when cut through, measuring an inch in thickness. Chambers much enlarged. Weight of the heart estimated at twenty ounces. Pulmonary artery natural size; valves properly formed; ventricular septum complete; mitral and aortic openings natural; valves healthy; large vessels in connection with the heart regularly distributed."

I regret that I have not a more complete history of this interesting case of uncomplicated patulous foramen ovale; but there is, I think, conclusive evidence that the presystolic basic murmur was the result of a current of blood through the foramen ovale during the auricular systole; and that the current was from the left to the right auricle is rendered nearly certain by the evidence of systemic venous fullness, with comparative arterial emptiness. The general lividity, the enlargement of the liver and spleen, and the cedema of the legs, are all results and evidence of systemic venous engorgement. The hæmoptysis, too, was probably a result of bronchial venous and capillary congestion; the bronchial veins forming part of the systemic venous system, and opening through the vena azygos and the left superior

intercostal vein into the superior cava. Again, the great hypertrophy of the right ventricle is to be explained partly by the extra effort required to propel the excess of blood on the venous side of the heart; partly, perhaps, by the impeded passage of a mixture of arterial with venous blood through the pulmonary arterioles: an impediment analogous to that which a mixture of venous with arterial blood encounters in the systemic arterioles. On the other hand, the deficiency of blood and of pressure in the systemic arteries is indicated by the radial pulse being "feeble and rather small", and by the "normal second sound (valvular click) being scarcely audible". There is, I admit, a deficiency in this part of my clinical record. I ought to have noted the second sound over the pulmonary and the aortic valves respectively. It seems probable that, while the aortic second sound was enfeebled by the want of tension in that vessel, the pulmonary second sound to the left of the sternum may have been intensified by the increased tension resulting from the hypertrophied right ventricle and the before suggested resistance in the pulmonary arterioles.

This case throws no light upon the disputed question of the relative share which venous turgescence and the admixture of venous with arterial blood respectively have in causing cyanosis. As I have already pointed out, there was abundant evidence of systemic venous engorgement; but there was probably also some mixture of venous with arterial blood in the left auricle and ventricle, and therefore in the systemic arteries. It seems likely that this would occur in the following mode. During the systole of the auricles, the right auricle, in consequence of the influx of blood from the left through the foramen ovale, would empty itself less completely than the left; then, during the succeeding auricular diastole, some blood would flow from the partially filled right auricle into the left. There would be a to-and-fro tidal flow of blood through the open foramen ovale, an active propulsion of arterial blood to the right during the auricular systole, and a passive flow of venous blood to the left during the auricular diastole. The general result would be an excess of blood in the right cavities of the heart and in the whole systemic venous system, with some mixture of arterial and venous blood in the left cavities and in the systemic arteries.

In a paper on Cyanosis (*Medical Times and Gazette*, September 1859), Dr. Tilbury Fox argued from *a priori* considerations that, if a patulous foramen ovale gives rise to a murmur, the murmur must be presystolic and synchronous with the auricular systole. It is only within the last few days that I found a reference to Dr. Fox's paper, and so had the opportunity of reading it. He will probably be interested to find in the case which I have here briefly recorded a confirmation of his theory published nearly twenty years ago.

Finally, I would remark that this case appears to me to afford confirmatory evidence in support of Dr. Gairdner's auricular systolic theory of the so-called *presystolic mitral murmur*.

### CASE OF UTERINE HYDATIDS TREATED BY THE INTRA-UTERINE INJECTION OF HOT WATER.

By LOMBE ATTHILL, M.D.,  
Master of the Rotunda Hospital, Dublin.

On the 18th of December last, I was asked to see a lady stated to be threatened with a miscarriage. She was a very delicate woman, a member of a family of whom several had died of consumption, she herself having suffered from ulcer of the stomach. On my visiting her, she stated that she had reached the twelfth week of pregnancy, had that morning been attacked with hæmorrhage, but was quite free from pain. On making a vaginal examination, I found the uterus to be of the size corresponding to the three months of pregnancy, and the os very slightly dilated. I ordered an ounce of the infusion of ergot to be given every third hour, and enjoined absolute rest. Everything went on satisfactorily for some days; the hæmorrhage ceased; she suffered no pain, and felt so well that I had much difficulty in inducing her to observe the recumbent posture. On the 20th, she began to go about; and on the 21st, having stood about a good deal, hæmorrhage again set in, this time profusely. On seeing her after the lapse of some hours, I found her very weak. She had lost a great deal of blood, and it continued to flow. The os was about the size of a threepenny-piece. There were not any pains, and nothing could be felt inside the os. I decided on plugging the vagina, and recommended the exhibition of ergot.

The next morning, I removed the plug, and was disappointed to find that no portion of the ovum protruded; but the os uteri was more patulous, and something soft could be felt inside it.

As she began to lose blood again, I decided to dilate the os and remove the ovum. With this view, I introduced a large sponge-tent. This I removed in six hours, but was again disappointed at finding that no ovum could be detected; while the hæmorrhage continued, and no uterine action had been excited.

Matters were now becoming serious. The patient had become very weak. Evidently the uterus must be emptied of its contents, whatever it was; and the hæmorrhage checked. After some hesitation, I decided on trying the effect of hot water, and accordingly introduced the tube of a Higginson's syringe into the uterus, and injected about a pint of water at the temperature of 112 deg. This within ten minutes induced uterine action. The pains were very sharp; and in a short time a mass, which on subsequent examination proved to be hydatids, was expelled. No further hæmorrhage occurred for about six hours, when, pains again setting in, slight hæmorrhage, followed by the expulsion of another mass of hydatids, occurred. From this time, no further trouble was experienced. The lady made a rapid recovery.

In this case, I was quite uncertain as to what the contents of the uterus might be. I had not previously heard of hot water being injected in cases of abortion; but my experience of it in *post partum* hæmorrhage was so favourable, that I resolved to try it in this case; the only other alternative being either plugging the vagina again or the continuing of the process of dilating the cervix. Either of these courses seemed to me, under existing circumstances, to be by no means free from risk.

My idea in injecting the hot water was to restrain the hæmorrhage, and I was not prepared for its acting as such a powerful stimulant to the uterus as to induce uterine action within the lapse of a few minutes. I need hardly add that I was much gratified by the result.

Since this case occurred, I have treated three cases of abortion accompanied by hæmorrhage in a similar manner. In two of these, the like results followed; namely, the exciting of uterine action and the arrest of hæmorrhage. In the third case, the hæmorrhage was arrested for twelve hours; but no pains followed. Hæmorrhage then recurring, I again injected hot water, with similar results. The ovum was not expelled till the lapse of twenty-four hours after the second injection.

Judging from these cases, I look on the treatment of hæmorrhage occurring during abortion by the injection of hot water (of a temperature not under 110 deg.) as perfectly safe; and that it is, on the whole, more reliable and satisfactory than any other method.

## CLINICAL MEMORANDA.

### CATGUT DRAINAGE.

IN reply to Mr. Chiene, I beg to state that my assertion that catgut drainage is most inefficient is based upon the following facts. 1. After the gut has become saturated by the contiguous fluids, it ceases almost entirely to drain at all. In proof of this, the following experiment may be performed. Place one end of a skein of catgut in a glass vessel containing water, and let the other end hang over the side of a second empty vessel: it will be found that very shortly the water begins to come over by capillary attraction, but, as soon as the point of saturation is reached, the flow becomes quite arrested, owing to the increase of friction which capillarity fails to overcome. 2. Catgut drainage is inefficient, because it does not remove the fluids from the deepest part of a wound, but only acts upon the fluids near the surface. This statement is true in all the cases in which I have seen catgut employed for the purposes of drainage, where a skein is used which traverses the wound from side to side but does not touch at any point the deepest parts of the incision: this, perhaps, might, to some small extent, be obviated by pushing one end to the bottom of the wound, and allowing the other end alone to hang dependent from the line of incision; but, if so placed, the deeper portion would in a short time become quite sodden, and no longer convey any of the fluids to the other from the end of the skein, even if it were possible, which I question, to maintain the gut in this position. 3. Catgut is inefficient, because it softens and breaks down before the wound has ceased to discharge. After a few days, the skein of catgut divides into two and comes away on traction at each end, and this very generally before drainage can be dispensed with. It may be affirmed that this constitutes no real objection, as it is an easy matter to introduce a fresh skein; but, in reply to this argument, I should say that such fresh introduction cannot take place without, in many cases, an undesirable opening up and separation of newly adhering tissues.

S. MESSENGER BRADLEY, Manchester.

## THE ELECTRIC TELEPHONE AS A MEANS OF TESTING OR MEASURING THE HEARING POWER.

MR. JAMES BLYTH, F.R.S.E., Secretary to the Society of Engineers of Edinburgh and Leith, has so adapted the electric telephone that, by a double ear-piece arranged so as to fit accurately to both ears or to one ear, without conveying the sound to the auditory nerves through the bones of the head (it can be made to conduct the sound through the bones as well), we can, by increasing or diminishing the resistance to the force of the sound-wave, accurately measure the hearing power of one or both ears. By interposing a certain number of resistance-coils in the conducting apparatus in a given instrument, or not, as required, we can obtain a normal standard. The diminishing of the resistance (the number of resistance-coils of a fixed value) would give us the hearing power of the auditory apparatus under examination. The telephone may also be made so as to improve or entirely supersede the present artificial means used for conducting and intensifying the sound-waves to the auditory nerve; a clear distinct sound, not too loud, properly conveyed to the auditory nerve, would be better heard and not so apt to do injury as many, if not all, of the ear-trumpets, etc., now in use do.

J. J. KIRK DUNCANSON, M.D., Lecturer on Aural Surgery at the Edinburgh School of Medicine.

## DEATH FROM ANÆSTHETICS.

IN reference to the case of death under anæsthetics which occurred in the Moorfields Ophthalmic Hospital in August last, cited (No. 16) in Mr. Dawson's excellent paper in the JOURNAL last week, I wish to make the following observations.

The apparatus used was Clover's smaller inhaler, with a slight modification, which I have introduced so as to avoid the inconvenience of having to remove the inhaler when desirous of giving a few breaths of fresh air. At the angle of the tube going to the bag is a small spring valve, on depressing which, and compressing the neck of the bag between two fingers, the carbonic acid is shut off, while the inhalation of ether mixed with air can be continued. If a little chloroform be poured on a piece of lint, and this held by the finger on the top of the depressed valve, you can have the additional anæsthetic action of chloroform removable at pleasure. I have used this apparatus now in fully one thousand cases, and have found it work very satisfactorily. In the case in question, the chloroform and ether were administered in this way. I do not consider that the patient had really inhaled more than five or ten minims of the former, while the ether-indicator had been gradually turned on from zero to two (*i.e.*, 50 per cent. of ether-vapour). On the first alarm, all anæsthetics were at once removed; but the ether-inhaler alone was then once reapplied for a few seconds, under the hope that it might act as a cardiac stimulant. As no voluntary respiration took place, it was removed. It will thus be seen, as was not rendered sufficiently clear in the former reports of the case in the JOURNAL of August 25th and September 1st, 1877, that the mixture was not a fluid one, and that the anæsthetic was not "applied on and off for some time after the first alarm".

I may mention that, as the above inhaler frequently obstructs the light in ophthalmic practice, Messrs. Mayer and Meltzer have supplied me with a long slightly flexible tube, which can be expeditiously attached between the face-piece and the ether-receiver, while the latter can be then hooked on to the administrator's button-hole. This is, of course, only to be used during the operation and after the production of sound anæsthesia.

R. MARCUS GUNN, House-Surgeon.

## CASE OF LEFT FACIAL PARALYSIS FOLLOWING EXTRACTION OF A LOWER MOLAR ON THE RIGHT SIDE.

J. F., AGED 25, warehouseman, had the second molar in the lower jaw on the right side extracted for toothache on January 13th, at 8 P.M., by a dentist in Glasgow. On the following day, he found what he described as a "stiffness" in the left cheek, which increased daily. There was a considerable amount of bleeding after the extraction, which continued for two days; it then ceased, and began again on the third day, and continued during the whole of that day and night; it then ceased entirely. As matters were becoming worse, he again called on the dentist on the 22nd, who pronounced the right side of the face to be at fault, prescribed a dose of salts, and desired him, if there were no improvement on the second day afterwards, to come back and have the first molar on the same side extracted, as this was thought to be the *causa morbi*—a small fleshy tumour appearing in

its centre. No improvement took place, and on January 24th he consulted me. I found complete motor paralysis of the left side of the face. He had great difficulty in eating, as the food always lodged in the left cheek; in drinking, as part of the fluid ran out of the mouth at the left side. The left eyelids were quite immovable; the left side of the tongue bung curving down and inclined towards the right side. The usual experiments in such a case gave the usual result. In addition to this motor paralysis, there was diminished sense of taste in the left side of the tongue.

A shade was placed over the eyeball to protect it, and quinine in grain-doses four times a day was ordered. Under this treatment, he rapidly improved, and on February 4th was able to return to business, there being then little trace of the malady. On February 8th, when I saw him last, he was perfectly well, both motion and sensation being completely restored. He had taken in all sixty grains of quinine.

REMARKS.—This case, so far as I have been able to determine, is unique as to its probable cause; for there can, I think, be little doubt that it was primarily due to the extraction of the tooth. At a previous time, he had had a tooth taken out, and then also there had been bleeding from the cavity for several days; but no other evil result had followed. Of course there remains the possibility of its having been a coincidence, not an effect; but what, then, was the cause? He was not in ill-health; he suffered at that time from nothing but the tooth-ache. In regard to treatment, this is the third case of facial paralysis in which I have administered quinine only, and used no counter-irritation, no blistering, and no faradisation; and they have all done well, and that rapidly. It is curious to note that from January 13th to 24th there are eleven days during which matters were undoubtedly becoming worse; and that from the 24th, when the treatment was begun, up till February 4th, when the cure was virtually complete, there are also eleven days. Was this a simple coincidence too; or is it an evidence of periodicity in what may be called traumatic paralysis?

J. STUART NAIRNE, Surgeon, Glasgow.

## CONGENITALLY IMPERVIOUS PREPUCE.

A CURIOUS case of congenital malformation was brought under my notice a few days since. In passing through one of the villages in this neighbourhood, I was called in by a woman, who asked me "to look at the infant of her neighbour, three days old, which had never passed water, and she felt sure there was something wrong". I learned that the mother had been attended by a midwife, who told my informant that "it would come all right".

On examining the child's penis, I found it was impossible to retract the prepuce to look for the orifice of the urethra, as the prepuce was impervious. After carefully verifying my opinion, I lifted the most anterior part with forceps, stripped it off with scissors, and, passing a director under the prepuce, slit it up, and retracted it. There was but little hæmorrhage; and on my visiting the child next day, I learned that he had urinated freely, and the wound was healing satisfactorily.

I cannot find an account of any similar case of malformation in any of the books on which I can lay hands.

J. INGLERY MACKENZIE, M.B. Cantab., Rugby.

## MOLLUSCUM CONTAGIOSUM.

I HAVE under my care at the St. George's and St. James's Dispensary an infant suckling, aged 8 months, the mother, and sister aged 7, all of whom are affected with true molluscum contagiosum. The disease first appeared in Louisa D., aged 7, on her hands and face. She nursed and played with the baby, who caught it, and communicated it from his face to the mother's breast. The father, James D., next caught it, having two tubercles under his left eye. The next and last to catch it was the brother, James D., who caught it from the baby. My colleague Dr. Thomas Fox has seen the mother, infant, and little girl. In order to satisfy himself fully on the nature of the tubercles, which were numerous on the face of the infant, he expressed the contents of several of the tubercles, which contained the characteristic sebaceous matter. This seems an unusual example of the contagious nature of true molluscum. It has spread through the whole family of five, one by one, having commenced in the little girl Louisa D.

FANCOURT BARNES, M.B.,

Physician to the British Lying-in Hospital.

VACCINATION.—Mr. T. Palmer Stephens has received a Government grant of £6:12 for successful vaccination in No. 1 District of the Westbourne Union. This is the fifth grant that has been awarded to Mr. Stephens.

## SURGICAL MEMORANDA.

## ANTISEPTIC SURGERY.

I READ with much interest Mr. Messenger Bradley's paper in the BRITISH MEDICAL JOURNAL of February 23rd on antiseptic surgery. That interest was deepened by the knowledge that it was in the Glasgow Royal Infirmary that antiseptic surgery was first introduced by Mr. Lister; and it was here he achieved his first, and, I believe also his greatest, triumph—greatest, because of the severity of the accidents he had to treat. The results he obtained were something marvellous; and eleven years' observation of his system has only confirmed me in awarding it the palm over all other methods which I have hitherto seen practised in the treatment of amputations, open wounds, etc. It is thought, however, by some that his mode of dressing is too cumbersome and complicated; and many, whilst believing in the theory, have attempted to simplify the practice. Mr. Messenger Bradley is one of these, and takes credit, through his statistics, for the method of antiseptic dressing he has used during the last two years, and claims for himself a success equal to that of any of Mr. Lister's followers. Happening to have finished my operation statistical table for last year, it occurred to me that a fair comparison might be made between his results and those of one of our surgeons who is a follower of Mr. Lister, and who faithfully carries out his plan of dressing even to its latest development. I therefore give his results for the same period that Mr. Bradley has given his—viz., from 1st January, 1876, to 31st December, 1877, tabulating them, so far as practicable, in the same manner, for the purpose of comparison, under the heading B. and F., the latter representing the Listerian mode of dressing.

TABLE.—Amputations.

	B.			F.		
	Recovered.	Died.	Total.	Recovered.	Died.	Total.
Forearm .. ..	3	0	3	1	0	1
Elbow-joint ..	0	1	1	0	0	0
Arm .. ..	4	0	4	6	0	6
Shoulder-joint ..	1	0	1	4	0	4
Hip-joint .. ..	1	0	1	1	0	1
Thigh .. ..	12	3	15	5	0	5
Both thighs ..	0	0	0	1	0	1
Knee-joint .. .	0	0	0	6	1	7
Leg .. ..	2	0	2	5	0	5
Ankle .. ..	8	0	8	1	0	1
Total .. ..	31	4	35	30	1	31
Mortality per cent.	11.42			3.22		

A glance at these tables will show the great superiority, so far as results are concerned, of Mr. Lister's method over Mr. Bradley's. This superiority is further brought out if we subtract from F.'s table those operations which are proved to be the least serious of the major amputations—viz., the one amputation of the forearm and the other at the ankle; and if we reckon as two amputations the patient who had both his limbs lopped off, we have thirty of the most serious operations in surgery with only one death, or a mortality of 3.33 per cent. The same analysis of the operations of B. gives twenty-four similar serious amputations, with a mortality of 16.66 per cent. As Mr. Bradley has in a manner said he would stand or fall by his statistics, I apprehend that those I have put against his fairly and unequivocally prove that his mode of dressing is not quite so good as that of Mr. Lister: and though his object in endeavouring to discover a simpler and equally efficacious method of antiseptic dressing is commendable, it must be acknowledged that he has as yet failed to do so. There is no doubt that Mr. Lister's mode of dressing is, if anything, more expensive than the ordinary method, though this depends a good deal on how it is used; but the extra expense is not so great as to appal or prevent hospital surgeons from adopting it, if by doing so they can reduce the mortality of amputations from one in nine to one in thirty-three.

M. THOMAS, M.D., Superintendent, Royal Infirmary, Glasgow.

CHESTER-LE-STREET.—There were 1,021 births and 440 deaths registered in this district during 1877. The death-rate is calculated at 20.9, which is 1.5 per 1,000 less than in 1876. There were 161 deaths of children under one year, which are equal to 15.7 per 100 births and 36.6 per 100 deaths; and Mr. Linton expresses his belief that these deaths were partially caused by early marriages, inexperienced mothers, and insufficient nurture; and notices the difficulty in getting good milk in villages.

## REPORTS AND ANALYSES

AND

## DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

## THE NEW ANTISEPTIC THYMOL 'GAUZE.

MESSRS. SQUIRE of Oxford Street write to us:—As many of your readers are no doubt interested in the new antiseptic thymol, and may wish to have some detailed information about it, its price, and the various forms in which its preparations are to be had here, we beg to inform you that, at the desire of Mr. Spencer Wells, we procured from Germany last January some of the thymol gauze prepared with spermaceti. We have supplied this gauze during the past month to several of Mr. Wells's patients, and, before ordering or preparing more, we were anxious to ascertain his opinion as to its utility. His reply (which we are permitted to send you) is to the effect that, "while appearing to be quite as trustworthy an antiseptic as carbolic gauze, it is free from the objections of stiffness, of irritating action on the skin, and of the disagreeable odour of the carbolic acid. It readily permits transudation of any fluid escaping from a wound, but does not appear to increase any secretion, nor to irritate the edges of a wound, nor the skin surrounding it. The wound, as a rule, does not require dressing until it is time to remove the sutures, and one more dressing is all that is required. A solution of 1 part of thymol in 1,000 of water appears to answer well for irrigation, for spray, and as an antiseptic bath for instruments and for sponges." A solution of thymol in water of a strength of 1 in 1,000 is all that is required. Thymol is soluble in warm-water in that proportion, and there is no separation on cooling.

As your readers may wish to know the price at which this gauze can be supplied, we may add that at present it is sold in packets, of six yards long by a yard wide, at 3s. 9d., or 8d. per single yard. When manufactured on a large scale, some reduction may possibly be effected. Thymol itself cannot be sold here for less than 2s. 6d. per ounce. Calvert's carbolic acid, No. 1, is 6d. per ounce; but if, as is expected, a solution of 1 thymol in 1,000 prove as efficacious as 1 carbolic acid in 40, the relative cost is in favour of thymol in the proportion of 5 to 1.

It may interest your readers to know that we have prepared for Mr. Wells an adhesive plaster, containing 1 part of thymol in 1,000 of plaster, which appears likely to fulfil the desire so often expressed of a non-irritating antiseptic adhesive plaster.

## PROBYN AND CO.'S PREPARATIONS OF IRON.

MESSRS. PROBYN AND CO., of 7, Pall Mall East and 55, Grosvenor Street, operative chemists, have forwarded us a neutral preparation of iron (oxychloride) in the colloid form obtained by dialysis; the iron being, it is alleged, separated from its combinations by endosmosis according to the law of the diffusion of liquids, and presented in a state as nearly as possible as it exists in the blood. They state with justice regarding this preparation—which can be procured in the form of syrup (dose for an adult, two teaspoonfuls, with or without water); or as a liquor (dose ten to thirty minims)—"that it is agreeable to take, and that it does not discolour the teeth"; and they add that it is easily assimilated, and does not disagree with the stomach or constipate the bowels.

We have before us medical reports, from an independent source, of cases in which this preparation in both of these forms has been administered, with marked benefit, to convalescents from scarlet fever and to others who were in need of ferruginous compounds. A good formula, our reporter adds, for prescribing the liquor consists of: Liquoris ferri dialysati ℥x ad xxx; glycerini ℥j ad 5ss; infusi quassie 5vj ad 5jss; tincture aurantii ℥j ad 5ss; to be taken three times a day.

## BAILDON AND SONS' APERIENT LOZENGE.

MESSRS. BAILDON and Sons, of 73, Princes Street, Edinburgh, have brought under our notice a fruit-lozenge rendered aperient by a few grains of the extract of Rhamnus Frangula or black alder, and made into a very palatable form by the addition of black currant paste. Since Mr. Baildon first introduced this bark to the notice of physicians and pharmacists in 1871, the concentrated decoction has been largely prescribed, and, we believe, is very generally satisfactory; and this aperient lozenge will probably contribute to extend the use of the black alder as an occasional aperient.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 9TH, 1878.

THE FACTORY ACTS AMENDMENT BILL.

PARTY government may possess great merits under a constitution like our own, when general politics, domestic and foreign, are the subjects dealt with; but its value and adaptability in determining on social questions, among which those relating to the health of the people may particularly be cited, where no party principles or prejudices should obtain, are, to say the least, very doubtful. Indeed, in our estimation, it will operate in such matters detrimentally to the public good. And has not every Parliamentary session produced a crop of examples? The recent debate in Committee of the House of Commons on the Factories and Workshops Bill can be adduced as a striking instance. This Bill had the advantage or disadvantage, according to the standpoint from which we regard it, of being introduced by the Home Secretary, and consequently ranked as a Government measure claiming support from the Government benches to a greater or less extent, irrespectively of the real value of its provisions; although, so far as party views between Conservatives and Liberals were concerned, it possessed a colourless character.

Moreover, its objects and its machinery had the approbation both of the members of the House and of the public outside. They were not new; for their importance and value had been well established through a long series of years. It put forth as a primary object the consolidation of a number of Acts of Parliament passed in various sessions during nearly fifty years aiming at the same end; viz., the physical well-being of the working-classes employed in factories and workshops, and particularly of the women, young persons, and children.

Yet, notwithstanding these circumstances and the character of the Bill, to anyone who followed the debate in the Commons, as reported, it was at once clear that party spirit intruded itself as a disturbing force, and brought about results to be deplored by those who desired the sanitary purposes of the Bill to be fully sustained and to be extended. The action of party was especially manifested in the divisions called for on amendments; for, although these might obtain some support on both sides the House, yet, when they did not perish prematurely under the veto of the Home Secretary, their struggle for existence was, on the demand for a division, speedily and effectually terminated by the strong reinforcement of members summoned from all parts of Westminster Palace by the division-bell to the aid of the right honourable gentleman. These trusty reserves could make no pretence to a knowledge of the arguments adduced *pro* and *con*, on the amendment submitted to their vote, and to but a slender one in respect of its purpose and intent. It was enough for them to know that they, as general supporters of the Government, were wanted to vote in favour of a measure introduced by a minister. Had the subject to be voted on been a political one on which Conservatives and Liberals differed as a matter of principle, then doubtless the opposition side of the House would have whipped up its reserves. But such was not the position occupied by the Factories Bill, which was regarded as an affair of its promoter and of manufacturers.

But there was a third party materially concerned in the measure; but one, alas! which the course of the debate showed to be held in light esteem by honourable members. This was the medical profession, specially represented by the large corps of factory medical officers engaged in the carrying out of those portions of legislation by which the physical health of factory operatives is sought to be maintained and improved. It is incumbent upon us, indeed, to acknowledge gratefully the recognition accorded to the certifying surgeons by Mr. Cross for their assiduity and efficiency in the discharge of their important functions, and the decided stand he made against some attempts to set aside medical supervision and control. And we have also heartily to thank Dr. Lyon Playfair and Dr. Cameron, together with those medical and other members of Parliament who joined with them in vindicating the claims of the profession, and in supporting the amendments proposed in the interests of the health of the working classes. We have, however, to lament the loss of almost every such amendment. They fell a sacrifice to party action.

The amendments brought forward were assuredly of a modest and moderate character. They sought little else than the reiteration of the same position and remuneration to the medical men to be employed under the Bill, as had in past times been accorded them under old Acts. They did, indeed, also point out ways wherein medical supervision and knowledge might be advantageously extended; but they made no demands for additional payment for such extended work. But all without success. The Home Secretary had set his face like a flint against alterations in his Bill. A proposal to introduce a new clause met at once with its quietus, on the ground that the Bill was simply a consolidating measure. If it were sought to sustain an existing statute or an established usage sacrificed by the Bill, the fate of the amendment was as inexorably sealed by the official refusal to be bound by it. Against such tactics, backed by a host of accommodating voters, it was hopeless for a small band of independent members to contend.

On the part of the promoters of the Bill, it was forgotten, or else kept out of sight, that it was in reality something much beyond a simple consolidation Bill; that to a very large extent it was the fruit of a lengthened inquiry by a Royal Commission empowered to report on the operation of the Factory and Workshops Acts, and to suggest amendments required in those Acts, as shown by the history of their past working. In short, it was largely based on the Report of that Commission, and actually adopted numerous changes therein recommended. Resistance to amendments to the Bill in its course through Parliament, on the score of its being simply a consolidation measure, was consequently out of place.

Had the opposition to the medical amendments been marked by nothing more than a determination not to entertain them, the profession, from past experience of its small weight in Parliament, might have bowed submissively; but it becomes a duty on its part to protest against the conduct and speeches of some honourable members in the course of debate on the Bill in question. It was, we maintain, insulting to the profession to derisively cheer the remark that a fee of sixpence for any professional service could not be proposed to the members of any other profession than that of medicine, and that lawyers would resent such a proposal. Quite true, and lawyers have to be thankful for their very large representation in Parliament; yet withal they should not mete out to members of another profession, not of less importance in the community than their own, a scale such as they would not tolerate.

But, however annoying this incident may be, it was outdone by the observations of Sir A. Lusk—whose name should not be forgotten—who argued on the regulations for cabmen, that, in lieu of the liberal fee of sixpence, as fixed by the Bill, for each completed half-mile above a mile from the residence of the factory medical officer, this gentleman should only receive that sum for each complete mile! It is

well that this member's medical constituents should know that he appraises them and their time by the standard of a London cabman. We write a London cabman, because a country one will not give his services under a shilling a mile. But what imparts a worse complexion to this matter is, that Mr. Cross promised to give the point his consideration—oblivious at the moment, we must presume, of the insulting comparison made in the proposal. For the right honourable gentleman to perceive it, must be tantamount to its being immediately scouted by him.

#### THE FUTURE GOVERNMENT OF COUNTY ASYLUMS.

WHEN any institution in this country happens to be exceptionally well administered, it is pretty safe to be reformed. When the administration of any institution happens to be a public scandal, it is very likely to be extended. Under the County Administration Bill, the government of our county asylums is about to be transferred from boards of visiting justices to hybrid boards of justices and Poor-law guardians, under whom it needs no prophetic faculty to foretell the fall of the English system of treating the insane poor.

On the last day of February, a deputation from the Medico-Psychological Association waited on Mr. Slater-Booth, to expostulate with him, on behalf of the Association, on his proposal to reconstitute asylum boards of visitors by substituting one-half of the number of visiting justices appointed by the Court of Quarter Sessions, or, if the number be unequal, the greater moiety, by persons elected by boards of guardians. The medical superintendents had taken the alarm, on their own account, at the proposal; and Drs. Manley and Rogers urged upon the President of the Local Government Board the necessity of protecting the interests of medical superintendents with regard to their retiring pensions from the parsimonious greed of the guardians. The President replied that his Bill in no way affected the salaries, pensions, or any other rights of the officers of asylums, and that he could not assume that the newly constituted asylum boards would or could be capable of any injustice in carrying out existing engagements. Dr. Bucknill, however, speaking on behalf of the insane poor, who are incapable of entering into engagements, and who are absolutely dependent upon the constituted authorities for their proper care and treatment, frankly told the President that he was going the way to spoil the government of medical institutions of which the public had just reason to be proud. If the medical superintendents are alarmed about their pensions, the insane inmate of the county asylum, if he could see the cloud which is gathering, might well dread the abstraction of sustenance and the diminution of comfort. Dr. Bucknill pointed out that insanity, which was involuntary, needed a different treatment, not only in degree but in kind, from pauperism, which was more or less voluntary; and that the spirit of the government of county asylums had been as different as possible from the spirit of the government of union houses; and that any fundamental interference with it would be disastrous to the interests of the most miserable and helpless members of the community. He pointed out, moreover, that this long discussed reform in the financial administration of county funds had nothing whatever to do with the care and treatment of the insane, which implied detention and control, and was as much a part of magisterial duty as anything else in which the liberty of the subject was abrogated for the general good, and that such administrative magisterial duties had never been asked of the guardians, who were, as a rule, most unsuited for their proper discharge. The proposed new boards, he said, composed of country gentlemen and guardians of the poor, half and half, would never act together comfortably to themselves or beneficially for the patients; but the course of events might very easily be foreseen. The guardians would elect their most fluent talkers and the men whom they thought their most stringent economists, whom the county justices would find not the most agreeable colleagues and would not choose frequently to encounter, so that very soon the government of the county asylums, or

of many of them, would pass entirely into the hands of the new and more self-asserting element, to the grievous detriment of the helpless inmates.

We very heartily trust that the county justices will estimate aright the real import of this proposed change in good time, and that whatever they may consent unto with regard to the county finances, they will strenuously resist any extension of their deposition from the administrative control of these county institutions, the proposal for which comes with so bad a grace and so strange an augury from the present Government, which is said to be that of the country party. We care not very much ourselves that country gentlemen should have agreeable colleagues ensured to them in any public business which they may undertake; but we do care very much that they should not be displaced by the blundering initiative of *doctrinaire* politicians, from administrative duties which they have, on the whole, discharged with admirable wisdom, liberality, and humanity; and we expect they have fostered the development of an important department of medicine, and have provided for the best attainable treatment of a vast number of those who are of all the most sick, and sorry, and suffering.

#### THE CRISIS IN THE ARMY MEDICAL DEPARTMENT.

IT is announced, as well it may be, that the question of the medical organisation of the army is engaging the serious attention of the Secretary of State for War. We reprint in another column statements of the main grievances of the medical officers of the department, inattention to which has brought about the present unpopularity of the department; and proper means have been taken to bring those statements under the notice of Mr. Hardy. Hitherto Mr. Hardy has been reputed to have pursued the system of taking the advice of one or two personal acquaintances in the medical profession, as to what are likely to be the best remedies for the discontent and disorganisation of the department; and it has been understood that that advice has not been always in accordance with the suggestions tendered to Mr. Hardy by the Association and other public bodies, in furtherance of the views of medical officers of all ranks in the medical department. Rightly or wrongly, it was very extensively reported at the time that one civil adviser was responsible for suggesting the short-service system, to be followed up by the weeding of the department at the end of ten years, with a *congé* and a bonus of a thousand pounds to those who were not wanted. It was made known to us that this scheme was in contemplation before it was finally adopted; and we took occasion at once to warn the authorities that no such proposition would be acceptable to the profession, or likely to succeed in recruiting the department or in contributing to its efficiency. The experiment was, however, persisted in, in spite of remonstrances, and with a disastrous result. Mr. Hardy has now, he announces, nominated a committee. There can be no doubt that the short service expedient must now be abolished, and that it must be replaced by the old system of continuous service, together with such conditions of service and of retirement as will make the service tolerable, and the flow of promotion and the conditions of retirement reasonably satisfactory. Within the lines of this programme, Mr. Hardy will find no difficulty in deciding upon the plan which will be likely to be accepted by the profession at large and by the department as satisfactory.

In a recent semi-official communication, it was intimated that the pressure exercised by this Association has done much to deplete the ranks of candidates for the Army Medical Service, and thus to make the requirements of the Service a matter of much more serious consideration for Ministers than they have been at previous times. If the *Army and Navy Gazette* notes this as a reproach, we, on the other hand, accept it as a warm tribute of praise. When the deputation of the Parliamentary Bills Committee waited on Mr. Hardy on this subject, it was very respectfully intimated to him

that, unless conditions of service reasonably satisfactory to the medical profession at large were granted, the whole influence of the Committee, for the Association and through the JOURNAL, would be exerted to maintain the fair requirements of the department. It is a source of great satisfaction that it has been found that that intimation, which was not in any sense intended as a threat, had nevertheless a very real meaning, and could not safely be ignored. The eminent men who accompanied the deputation, and the pains taken to elaborate all the points in the statement submitted to Mr. Hardy, were sufficient vouchers that the Parliamentary Bills Committee did not address the Minister without having very carefully investigated the whole question; and it is unnecessary to say that its relations with the most eminent members of the Army Medical Department, as well as with medical men of all ranks, are such as to enable it to get information from the most various and extensive sources as to what may fairly be considered the legitimate demands and requirements of the service. When so presented, we believe that no Minister can now afford to treat those representations with anything less than attentive and respectful consideration. At any rate, the former disregard shown by Mr. Hardy on many leading points which have been urged upon his attention as essential to the fair settlement of the question, has resulted most unsatisfactorily for the welfare of the army, and for the comfort and safety of both officers and soldiers, whose interests must always be the first as well as the principal sufferers from any deficiency in the quantity and quality of the medical attendance which is essential to the health and well-being of the force. The urgency of the situation will give Mr. Hardy the best possible reason for treating the question afresh, and taking a new departure from a more extended and generous point of view; and his appointment of a committee, together with the conciliatory tone of his speech in moving the estimates, indicates that Mr. Hardy has awakened to a sense of the gravity of the situation. With this object, we submit the list of grievances to be found on page 346; and we trust that they will be considered in a generous conciliatory spirit, and with the desire of bringing about a permanently satisfactory organisation of the department.

THE name of Dr. E. H. Greenhow has been added to the Royal Commission recently appointed to inquire into the working of the Penal Servitude Acts, in the place of Dr. Guy, who, we regret to hear, is disabled by severe illness.

WE understand that the Committee on the Army Medical Department, mentioned by Mr. Gathorne Hardy when introducing the army estimates, consists of Mr. Thompson, C.B., Assistant Under-Secretary of State for War; Sir William Muir, K.C.B., Director-General Army Medical Department; and Mr. Robinson, War Office Actuary.

A TELEGRAM from Rio Janeiro, dated March 1st, states that yellow fever had been raging there. From forty to forty-five deaths in the city had been registered in the first fortnight of February.

IT will be seen that the first award of the Marshall Hall Memorial Prize of the Royal Medical and Chirurgical Society has been made to Dr. Hughlings Jackson, for his investigations into the Pathology of the Nervous System. Few physicians have added more by their labours to the scientific progress and contemporary reputation of British medicine than Dr. Hughlings Jackson, whose labours have always been carried out in the true scientific spirit, and accompanied by a reserve and modesty which have heightened their value. This award will be received throughout the profession with high approval.

WE understand that the Fothergillian Gold Medal of the Medical Society of London has been awarded to Dr. J. Milner Fothergill, Physician to the West London Hospital, for his essay on the Physiological Antagonism of Certain Poisons.

THE silver medal of the same Society has been awarded to Dr. J. Althaus, for the best paper of the session; the subject of his paper being the Lesions of the Anterior Cornua of the Grey Matter of the Spinal Cord.

A PROJECT is on foot, which does not seem to be very wisely founded and may possibly not come into practical operation, for establishing another lying-in hospital in the west end of London.

MEANTIME, we hear that considerable changes are likely to be made in the management of the General Lying-in Hospital, York Road, with the view to increasing the efficiency of that old-established and endowed charity.

THE changes effected in the management of the Queen Charlotte's Lying-in Hospital have, we hear, operated most satisfactorily in the reduction of the rate of mortality, and in the production of excellent vital results such as have not always been attained at that institution.

SOME dissatisfaction has, we hear, been caused at the Charing Cross Hospital by the resolution of the Governors to accord to the Senior Surgeon a further extension of five years, in addition to one already accorded to him, after the completion of the term of age at which, in accordance with the rules, he should cease to act as surgeon.

WE understand that a Committee of Council is summoned for Wednesday next, and that before it will be laid a proposal for calling a special general meeting of the members to discuss the propriety of framing a by-law for the purpose of carrying into effect the vote of the Association of 1876 against the admission of women to the Association, and also of taking into consideration the case of the two ladies who were admitted prior to that vote. At the same meeting of the Committee of Council, the recent correspondence relating to the official Report of Proceedings of the Committee of Council will come under notice.

A SPECIAL general meeting of members can only be summoned by the Committee of Council, who have power to convoke it spontaneously, or who must convoke it upon the requisition of fifty members. By-laws may of course be recommended for adoption at such meeting; but such by-laws can only have legal effect when adopted, after two months' notice, by the annual general meeting.

A LETTER from Dr. W. O. Markham, which we have been compelled, from pressure on space and late arrival, to print in small type in another column, deals with the question of the two lady members of the Association which has already been much discussed in our columns.

DR. HENRY BROWNE has resigned the office of Physician to the Manchester Royal Infirmary, after a tenure of a quarter of a century, during which long period he has rarely been absent for a day from attendance to his hospital work. His resignation creates no vacancy, as the staff is for the future to comprise but four full physicians. It is true that there is a proposition to increase the number of assistant-physicians to three; and if this be carried, we understand that Dr. Ross, who is at present pathologist to the hospital, and who is well known to the profession by his important work on *Graft-Theory of Disease*, and other varied work, will be a candidate.

DR. COHNHEIM, Professor of Pathological Anatomy in Breslau, has accepted an invitation to the same chair in the University of Leipzig; and Dr. Ponfick, Professor in Göttingen, has been invited to fill the vacancy thus created at Breslau.

IT has been determined to hold the sixth session of the International Medical Congress in Amsterdam, in September 1879. A Committee, of which Professor Donders of Utrecht is President, has been formed to make the necessary arrangements.

## THE DENTAL PRACTITIONERS' BILL.

THE Dental Practitioners' Bill was set down for adjourned discussion on the second reading on Tuesday last, but did not come on, its promoters being unable to keep a House. This Bill may be counted among the things of the past. It is improbable that it will have a second reading; and, although it has been greatly modified, to meet the objections urged against it by our Parliamentary Bills Committee and by other bodies, it may be accepted as certain that it will not pass into law. We should think this to be regretted, now that the Bill has been modified in much that was seriously open to objection, and remained only as a Bill destined to afford reasonable organisation for a profession which much needs such organisation, but that we have reason to believe that such organisation will be provided for the dental profession without independent legislation on their part. The support given by Mr. Cross to the second reading of the Dental Practitioners' Bill was, we understand, not intended to signify the Government approval of that Bill, although it was universally so interpreted. The Bill had not, and has not, been submitted to the General Medical Council; and contains even now, as amended, clauses to which that body would be unlikely to assent. There has been, however, a very inconvenient practice pursued in promoting this Bill, of alleging individual assents, supposed to convey official approval by corporate bodies, and this on insufficient grounds.

## BOARDING-OUT OF PAUPER CHILDREN.

WE see with great satisfaction that the boarding out of pauper children, which has long been firmly established in Scotland, and largely also in Ireland, is steadily making its way in this country, and is gradually overcoming the prejudice and reluctance in the official mind which impeded its adoption. Nothing can be more lamentable than the physical results of the herding together of vast masses of children in district schools, away from all the influence of home, and destitute of the healthy and necessary action of family life. Miss Preusser of Windermere, Miss Hill, in her *Children of the State*, and some others, led the way in this great measure of reform, and they have been zealously aided by many others who have helped them to carry their views into practical effect. The last report shows that the system is gradually extending, and that it is being employed with great success by the Guardians in Birmingham, in Leeds, at Bristol, and at the East end of London, and in numerous other unions. We recorded only lately the fact that, notwithstanding all that has been done to root out ophthalmia from the district schools, a well known oculist recently reported that all the five hundred children at Mitcham were more or less afflicted with ophthalmia. The endemic character of this contagious local affection is probably as good a test as could be devised of generally low vitality; and, indeed, we venture to doubt whether the most perfect sanitary arrangements which could be devised will ever equal in efficiency for each child the more ductile, varied, and adaptable conditions of family life found in boarding out, even among poor families. Of course, thoroughly organised supervision is a primary necessity for preserving the health of children in boarding out, as well as for other objects in view.

## VENTILATION OF PUBLIC BUILDINGS.

IT is difficult to say whose grievances are the greater in the law courts and other public buildings: those of the persons ventilated, or of the expert in charge of the ventilation. For the most part, the latter is expected to do that which is impossible, viz., to provide an adequate flow of air for the respiration of a mass of human beings packed like herrings in a barrel, without passing through the chamber air at any considerable speed, when it is declared to produce draughts, or too dry, or too moist, or too warm, or too cold air. The solution of the problem would already be impossible in this variable climate, and with the great susceptibility of all persons to rapid currents of air, and their morbid fear of them, even if human beings had approximately similar feeling and taste in respect to temperature and quality of the air in

rooms; but the fact is that one man freezes from cold where another dissolves from excessive heat, and each attributes his discomfort to defective ventilation. Elderly men, such as the Lord Chief Justice, like to be kept very warm, and have a particular horror of any rapid movement of air; and it is very well known that, in the archives of the ventilation department of the law courts, may be found numerous missives from that and other eminent judges, directing every window of the court to be shut at a moment when other persons in the court are suffocating from what they consider to be want of air, and are penning heated missives of complaint to the public papers. Of course, the usual remedy against defective ventilation is found where a sufficiently large cubic space can be given to each individual, since, under these circumstances, the air required for the consumption of each person can be supplied without frequent renewal. But, where a large number of persons are packed into one room, and where it is necessary to provide them all with 8,000 or 10,000 cubic feet of air for breathing per hour, the air needs to be changed from minute to minute; and the problem of supplying rapid currents of air, at a temperature of particular dryness or of moisture to please every one, has never yet been solved. As, however, persons whose word is law are mainly seniors, it will generally be found that they are satisfied with a much less rapid change of air than their juniors, and that they require a higher temperature. In other words, to please them the younger men suffer; and that we take to be the moral of the complaints both in the law courts and in the House of Commons. Possibly, however, in the new law courts, arrangements will be made more nearly resembling those of the Houses of Parliament, where the ventilation is as near perfection as may be, although it is all the same exposed to periodical attacks of grumbling, and requires the constant attendance of an intelligent expert.

## ARMY MEDICAL DEPARTMENT.

WE find some difficulty in reconciling the two different statements which Mr. Hardy seems to have made in the House of Commons respecting the number of vacancies existing in the Army Medical Department last week. He stated, in reply to Dr. Ward, according to the reports, that for forty vacancies in that department there were only nineteen candidates forthcoming, leaving a deficit of twenty-one void appointments in that department. Since the 11th of last month, when only these nineteen candidates were then forthcoming, the retirements from the department have outnumbered the reappointments from the half-pay list, and no other candidates have been forthcoming. We do not understand clearly, therefore, by what process this deficiency, which, in reply to Dr. Ward, Mr. Hardy stated at a minimum of twenty-one, became a few nights afterwards eight. No doubt there is an official explanation to be had; but it might be interesting if it were made public.

## MOSQUITOES AND MEN.

THE mosquito has been regarded as a particular nuisance by man wherever they have met. The bite of this peculiarly objectionable insect has an irritating effect upon most people, over and above the mere discomfort produced thereby. But it would appear that mental disturbance and systematic bleeding are not the only injurious actions which the mosquito can and does exercise upon us. From what was said at the Pathological Society on Tuesday evening, it would appear that the mosquito is the means of spreading the *filaria sanguinolenta* amongst human beings. They suck up this tiny entozoon with the blood of their human victims; and the female mosquitoes, after their banquet, go to the rivers to deposit their eggs. In doing so, the filaræ and their larvæ find their way into the water, and again to other human beings who drink it. In order to ascertain how far the mosquito is thus a carrying agent of disease from man to man, a patient known to have the filaria in his blood was placed alone in a chamber, and an opportunity furnished to mosquitoes to feed upon him. After that, the spoilers were captured and dissected, and in the stomach of one no fewer than one hundred and twenty filaræ were

found. This newly found relation of the mosquito to man adds materially to its objectionableness; for not only does it feed upon us, but it helps to spread among us an entozoon which is known to cause a definite series of unpleasant pathological consequences by its presence in the blood.

#### FEVER IN KENSINGTON.

FOUR deaths from "typhus", so-called, have been reported from Kensington within the last two months, without any other inmate of the houses having been infected, or any unsanitary conditions being discovered on inspection. Dr. Dudfield, believing from these circumstances that they were not cases of typhus, made special inquiry of the medical attendants, and was informed that two were typhoid, another doubtful; and the fourth was certified as a death from "typhus-rheumatic fever". In this latter case, Dr. Dudfield believes that death arose from heart-disease supervening in the course of rheumatic fever. It is well known that much looseness still prevails as regards the giving of certificates for febrile diseases; and that "typhoid", and occasionally "typhus fever", are certified as causes of death in connection with pneumonia, rheumatic fever, puerperal fever, scarlet fever, and other similar diseases. This practice should be discontinued, and the word "typhoid" either be used only as a synonym of "enteric fever", or not employed at all.

#### SEWER-GAS.

DURING last year, there were numerous cases and many deaths from diphtheria in the Withington district, which in almost every case were caused or aggravated by nuisances, such as waste-pipes passing direct from the nursery to the drains, ash-pits immediately below the bedroom windows, untrapped entrances to the drains, and in one case by a choked and broken drain; the most frequent nuisance being waste-pipes in the house passing directly into the drains. In connection with this, we may mention the frequency with which this disease has occurred amongst the inmates of bedrooms which were near to open joints in rain-water water-pipes, or to small pipes receiving the rain-water from the top of bay windows. Dr. Railton, the medical officer of health, also states that the streams running through the town are highly charged with excrementitious matters of all kinds, which may have caused a predisposition to the disease, and which have been gradually rendered worse year by year through increase of the population.

#### JAIL-BIRDS.

DR. JOHN MOORE of Belfast has published some very striking figures, indicating the costly and ineffectual nature of the present practice of dealing with criminal habitual drunkards by repeated short periods of imprisonment. The figures are very eloquent. On October 1st, 1877, there were in Belfast Jail ten prisoners who had had one thousand six hundred and thirty-six convictions recorded against them, an average of one hundred and sixty-three convictions. They had cost while in prison £1,780. In 1875, there were a thousand persons in prison in Ireland against whom in all five thousand convictions had been recorded. Of these, two hundred and fifty had been imprisoned in Belfast Jail; their imprisonments amounted to eleven thousand, and their cost in prison to £14,000. These figures, which may be multiplied indefinitely, speak eloquently of the utter uselessness of the present mode of dealing with habitual drunkards by sending them to prison for short periods: a method which, as Dr. Moore points out, is neither punitive, curative, nor preventive. He recommends that any person convicted of drunkenness four times within twelve months should be considered an habitual drunkard. Habitual drunkards should be committed like prisoners under remand; but the remand should be for a period of not less than three months. When so remanded, they should be set to work in prison; and those who earn more than covers the cost of their maintenance should have such sums placed to their credit, to be applied to their use after their discharge, or given to their families in the meantime if such were dependent on them. Habitual drunkards, when discharged before a period of three

months, should be placed under police supervision, which would extend over twelve months. Short sentences, he points out, do not permit the effects of the drink to be eliminated from the system. The discharge of such persons at the end of a short term tends to break down any moral reformation, should such have begun. It prevents any system of remunerative labour being carried out in prisons; and it exposes the public to suffering from crimes committed which would otherwise be prevented. Dr. Moore's suggestions are set forth at greater length in an excellent pamphlet on *Prison and Prison Discipline*. They have received the approbation of many eminent prison authorities, and certainly have this practical side to them, that they propose to take measures to bring about a reformation of a class of habitual drunkards who by their acts have already brought themselves within the arm of the law, and whose present treatment now involves enormous cost to the country, without any adequate deterrent or reformatory result.

#### SMALL-POX AT HARWICH.

THE hopes of a clean bill of health last week at the Temporary Hospital, Harwich, have been disappointed; for, besides two fresh cases, the admission of which we recorded last week, two more appeared on Wednesday in Dovercourt, a suburb of Harwich, just at the time when the authorities were congratulating themselves on the complete freedom of the town from small-pox, as the six cases in hospital were all that remained in any stage. The two cases admitted last week were of a favourable character. The man, a severe case, reported last week, died, as anticipated.

#### TYPHUS FEVER AMONG RUSSIAN SOLDIERS.

THE following telegram, dated Jassy, February 28th, has been received at St. Petersburg: "The number of typhus cases among the wounded soldiers who were brought to Jassy in the course of January and February has considerably increased, and now reaches 19 per cent., whereas it was previously only 5 per cent. All the railway-carriages on the Fratisti-Jassy line are infected, and disinfecting processes have only been applied to a partial extent, as they appear to have no effect. All along the Simnitsa and Fratisti line, large numbers of unburied corpses are lying in a state of decomposition. It is therefore absolutely necessary that the Russian troops returning from Bulgaria and Roumelia should be conveyed by way of the Black Sea, and not *via* Simnitsa, Fratisti, and Jassy. The Sanitary Committee in Jassy remains inactive."

#### THE EDUCATION OF MIDWIVES.

THE education of midwives appears to stand in the Sandwich Islands in the same position as it does in Great Britain, and seems to be the source of similar difficulty. At a coroner's inquest reported in the *Timaru Herald*, it appears that a midwife was in attendance in a case in which there was rupture of the uterus; and, after hearing the evidence of the midwife and the medical man, the jury added to their verdict that they quite disapproved of uncertified females acting as midwives without the supervision of a duly qualified medical practitioner. Hence in this point they are no better off in Timaru than we are in Great Britain, and are precisely in the same state of frequent expression of public opinion on the subject, with which every one agrees, while nothing is done.

#### THE METEOROLOGICAL SOCIETY.

AT the monthly meeting of this Society on Wednesday, February 20th, Dr. Tripe read a paper on the Winter Climate of some English Seaside Health-Resorts. The places selected were Scilly, Torquay, Penzance, Guernsey, Barnstaple, Ventnor, Llandudno, Ramsgate, and Hastings; and the climatic features of each were compared with those of London. The results of the discussion may be briefly summed up as follows. The mean daily winter temperature of these seaside places, and especially of those situated on the coast of Devon and Scilly, is higher than at London. The mean daily maxima and minima are also

higher, and especially the latter; so that the daily and monthly ranges of temperature are smaller. The mean humidity is less; the general direction of the wind about the same; but the number of rainy days and the rainfall are greater at the seaside. As regards the wind, therefore, the chief point to be especially noticed is the amount of shelter afforded by high land, as at Ventnor, and especially of protection against the stormy and cold winds which ordinarily prevail at the end of February and in March. The soil also should be considered, as heavy rains at gravelly and chalky places are not so objectionable as on clayey ground. The discussion on this paper was adjourned until the next meeting, which will be held on March 20th.

#### THE LANCASHIRE AND CHESHIRE BRANCH.

THE intermediate meeting of the Lancashire and Cheshire Branch of the British Medical Association, held at Oldham, on Tuesday, March 5th, was highly successful. About eighty members were present at the reading of Dr. Broadbent's interesting paper on the Mechanism of Speech. Several short papers followed; and keen interest was evinced in the demonstrations of Drs. Ross and Dreschfeld of the Physiology and Pathology of the Spinal Cord by means of projection on to the screen. Subsequently the members dined together at the Angel Hotel, and much gratification was expressed at the character of the meeting.

#### HOSPITAL FOR DISEASES OF THE THROAT AND CHEST.

THE special meeting, convened through the action of a requisition of twenty subscribers to this institution, was held on Saturday; Lord Calthorpe, President, in the chair. After the report had been read, the Rev. H. R. Haweis, in accordance with a notice on the agenda paper, moved the first resolution, which was to the following effect: "That, considering the circumstances which led to the formation of the Committee of Inquiry, and the manner in which the investigation was conducted (as detailed by the Committee of Management at the annual meeting of subscribers, held February 9th, 1878), and considering further that no copy of the report of the so-called Committee of Inquiry was ever forwarded to the Committee of Management, this meeting declines to receive such report." This was seconded by Mr. Sterne. Captain Hughes Hallett moved, as an amendment: "That the report be read and not necessarily received", which was also duly seconded. After a good deal of discussion, some of it of a personal nature, the amendment was rejected by a large majority; whereupon Sir Charles Legard stated that he could not avoid the conclusion that the meeting, in refusing to allow the report to be read, were afraid to meet the serious charges against the administration, which it was admitted that it contained, and left the room, together with those who were in favour of the report being read, amongst whom was Dr. Semple, one of the physicians of the hospital. It is to be regretted that this report, which is entitled to much consideration from the subscribers, inasmuch as it is the report of high officers of the institution, such as Lord Clarendon, the Duke of Grafton, Lord Dunmore, together with Sir William Gull, appointed at the instance of the Prince of Wales, was not read to the meeting and fairly discussed; a course which we have throughout steadily urged upon the well-wishers of the institution, as being the most consistent with the ordinary practice of public institutions, and most likely to conduce to salutary reform. It is obvious that the refusal to read the report, and fairly to face its conclusions, must greatly weaken any claims which this institution may have to public and professional esteem; although we have already stated that the conclusions of the report are, in our opinion, seriously in conflict with the evidence adduced, and very unjust to Mr. Morell Mackenzie.

#### HUNTERIAN SOCIETY.

AT the recent annual meeting of the Hunterian Society, the following gentlemen were elected officers for the ensuing year:—*President*: T. H. Crosby, M.D. *Vice-Presidents*: Walter Moxon, M.D.; J. McCarthy, M.B.; Buxton Shillito, Esq.; G. Lichtenberg, M.D. *Trustees*: H. I. Fotherby, M.D.; D. de Berdt Hovell, Esq. *Orator*: W. Rivington, M.S. *Librarian*: P. L. Burchell, M.B. *Secretaries*: R. Clement

Lucas, B.S.; Stephen Mackenzie, M.D. *Council*: J. E. Adams, Esq.; Fletcher Beach, M.B.; A. E. Durham, Esq.; T. R. Fendick, Esq.; R. Fowler, M.D.; J. Greenwood, M.D.; A. Galabir, M.D.; C. R. Nicoll, M.D.; A. H. Smee, Esq.; G. J. B. Stevens, Esq.; W. C. Toulmin, Esq. The annual dinner of this Society was held at the Albion Tavern on February 22nd, when the retiring President, Mr. A. E. Durham, took the chair. He was supported by Professor Owen, the President of the Royal College of Surgeons, the President of the Medical Society, and many other distinguished members of the medical profession.

#### MR. LIEBREICH ON OIL-PAINTINGS.

IN an extremely interesting and brilliantly illustrated lecture at the Royal Institution on Friday last, Mr. Liebreich, Ophthalmic Surgeon at St. Thomas's Hospital, whose accomplishments in the arts almost rival his scientific acquirements, discussed a curiously-interesting subject, to which he has devoted a good deal of his leisure, and which might be aptly described as the pathology and therapeutics of oil-paintings. Adopting a strictly scientific medical method, he discussed in the most complete manner the pathology of the various diseases of oil-paintings, separating those which are constitutional from those which are accidental. He investigated their causes, and wound up by some rapid and singularly successful demonstrations of methods of restoration derived from this study. The number of medical men who find time, in the midst of busy practice, to devote their leisure to artistic and scientific pursuits, sometimes cognate and sometimes altogether diverse from their medical studies, is on the increase; and the feeling which existed that medical men should, as far as possible, in their pursuits, stick to the shop, has yielded to the more general spread of culture, and to the opinion that many-sided interests and varied culture are not only compatible with the highest grades of skill, but may indirectly conduce to it.

#### TREATMENT OF ELEPHANTIASIS BY NERVE-SECTION.

DR. THOMAS MORTON of Philadelphia has successfully treated a case of elephantiasis Arabum of a very marked character, in which ligation of the femoral artery had been ineffectually tried, by a new operation consisting in the excision of one-and-a-half inches of the sciatic nerve at the upper third of the thigh. On November 9th, prior to the performance of the latter operation, the leg measured twenty-one inches in circumference. On January 3rd, two months after the excision of the nerve, it was found to be but twelve-and-a-half inches in circumference—a reduction of eight-and-a-half inches; and the thick ichthyotic crust which covered the limb from the knee to the ankle and foot had desquamated, leaving a perfectly clean, soft, and pliable skin beneath. The sensibility of the larger part of the limb operated upon was but slightly impaired. On the whole, the result of this novel and well-conceived proceeding appears to have been most satisfactory.

#### ANTISEPTIC DRESSINGS IN GERMANY.

AN article with this title, in a recent number of the *Progrès Médical*, gives an account of the antiseptic materials which seem to have superseded Lister's carbolised gauze, and which claim for themselves greater economy, diminished irritability, and freedom from liability to poisoning. Thiersch has come to the conclusion that a saturated solution of salicylic acid—that is to say, 1 to 300—prevents putrefaction of the blood and secretions of a wound, while it produces no irritating effect upon recent or granulating wounds, and gives no cause for alarm by the passage of salicylic acid into the circulation. He uses a solution of salicylic acid for washing instruments, and the hands of the operator and his assistants. The spray is of salicylic acid, which proves, however, very irritating to the mucous membranes of the persons engaged in the operation. The dressings are simple enough. Salicylic acid being non-irritant, no protective is required, according to Thiersch; but, at least in healing surfaces, the protective has the additional advantage of protecting the granulations and the delicate new

epithelium covering them from the danger of sticking to and being injured by the dressings or their removal. But Thiersch uses no protective. He places immediately upon the wound a layer of wadding containing 3 per cent. of salicylic acid; then another layer containing 10 per cent. Blaser, pharmacist to the hospital at Leipzig, employs the following formulæ for the preparation of these dressings. For the 3 per cent. wadding: Dissolve 750 *grammes* of salicylic acid in 7,500 *grammes* of alcohol of specific gravity 830. Add 150 *litres* of water at 70 to 80 deg. cent. (158 to 176 deg. Fahr.) Place in the mixture 25 *kilogrammes* of cleaned wadding. For the 10 per cent. wadding: Dissolve 1 *kilogramme* of salicylic acid in 10,000 *grammes* of alcohol of specific gravity 830. Add 60 *litres* of water at 70 to 80 deg. cent. Place in the mixture 10 *kilogrammes* of cleaned wadding. To saturate the wadding, he uses a shallow vat, in which it is laid layer by layer, taking care not to put in more than two or three *kilogrammes* at one time, and that one layer is well saturated before the next is put on. When all are in, they are to be turned over, so that the bottom one comes to be at the top and left for ten minutes; then removed; and, as they cool, the salicylic acid crystallises out. Finally, the wadding must be dried in a warm place. Thiersch has also tried a dressing composed of jute saturated with salicylic acid; but the powder was disengaged in large quantities, and was extremely disagreeable to the surgeon; and it proved, besides, too permeable to the secretions of the wound, being less cohesive and fine than the wadding; so Thiersch himself has abandoned it. Köhler, Medical Director-General of the Prussian Army, has suggested the use of carbolised jute. The preparation is very simple. The jute is made up into cakes one to two *centimètres* thick, fifteen *centimètres* in diameter, and weighing four or five *grammes*. They are left to soak some hours in a five per cent. solution of carbolic acid, and are then left in two per cent. solution until required for use. To apply them, the wound is covered with a slip of gutta-percha instead of the protective; then some cakes of jute; and the whole is kept in place by a gauze bandage. It requires to be renewed every three or four days; earlier, if there be discomfort, or the discharge have come through; later, if the patient remain well. It is calculated that Thiersch's wadding is about a third cheaper than Lister's gauze, while Koehler's dressing only costs about a twentieth of the price of the latter. Cheaper and at the same time efficient antiseptic dressings are desiderata, and we think that these may be found as useful here as they are said to be in Germany.

## SCOTLAND.

THE Edinburgh Institution for the Relief of Incurables exhibited a report, at its annual meeting held last week, which shows how much good may be done by helping people at their own homes. They annually distribute among the poor suffering from incurable diseases the sum of nearly £1,000, in donations of £1 a quarter, to upwards of two hundred recipients. The cases are carefully inquired into, and the whole business of the society is conducted on a satisfactory and very economical footing.

A GENERAL meeting of the managers of the Inverness Northern Infirmary was held last week, and a committee was appointed to report on the desirability of appointing a medical man of experience to take charge of the institution, and to report on what rearrangement of the staff was advisable. The Secretary reported that the excess of expenditure in the year 1877-78 over income was upwards of £700.

### ASYLUM FOR IMBECILE CHILDREN.

AT the seventeenth annual meeting of the supporters of this institution, it was stated that the buildings may now be considered as completed, the additional accommodation proving most useful in allowing a more distinct classification of the inmates, and in supplying work-rooms, class-rooms, and rooms for amusement, the want of which had long been felt as a serious drawback to the children. A portion of the

new buildings had been furnished, and was now occupied. The directors were anxious to have the whole of the new buildings finished, so as to admit of the reception of a largely increased number of applicants from the election-roll; but, in order to do this, about £1,000 was necessary for the purpose. Dr. Ireland, in his report, stated that there were 101 patients—63 males and 38 females—in the institution. During the year, there had been 35 admissions, 21 discharges, and 3 deaths. An unusually large number of those admitted last September were of the uneducable class; and that very little could be expected from a good proportion of the inmates, might be guessed from the fact that there were at present in the house twenty-six who were either mutes or spoke very little. The work of training and teaching the children had been carried on with patient industry during the year. The finances were in a satisfactory state.

### THE AIR OF GLASGOW.

AFTER some delay, the reports of Mr. Dixon for the months of September and October last have just been issued. They present no essentially striking features, as compared with the statistics previously reported, except that, so far as sulphur in combination is concerned, the quantity present in the air during October was in excess of any of the months since May last. The highest amount of this impurity noted was .42. The substances are estimated in one hundred cubic feet of air and expressed in weight, the unit employed being the *milligramme*. There has been comparatively little fluctuation in chlorine. Organic matter, as represented by nitrogen in the form of ammonia and albuminoid ammonia, was high in September as compared with October, but not in excess of what has been previously found. The stations at Stirling Square and the Calton come in highest in that respect.

### THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

IN the Registrar-General's quarterly return of births, deaths, and marriages in Scotland during the last quarter of 1877, we find that births occurred at the rather high rate of 3.51 per cent. of the population; the births were, indeed, far more numerous than during the corresponding quarter of any of the last ten years. The death-rate, on the other hand, was decidedly below the average; deaths occurred at the rate of 2.01 per cent. of the estimated population, the average death-rate during the corresponding quarter of the last ten years being 2.193 per cent. Among the deaths in the eight principal towns, zymotic diseases claim only 15.9 per cent., indicating a very satisfactory state of public health; only three deaths were from small-pox; typhoid was far more common than typhus; but the ruling epidemic of the quarter was whooping-cough. Diseases of the respiratory system caused a very large proportion of deaths.

### PROFESSOR BALFOUR.

WE understand that a movement has originated in the University of Edinburgh to procure a portrait of Professor Balfour, in recognition of his services to the University in having for thirty years acted as Dean of the Medical Faculty. This movement has been joined in by the Fellows of the Royal Society of Edinburgh, in recognition of their part of the services he has for many years rendered to the Society in the character of Secretary. It is to be hoped that the combined efforts of these important bodies will make this movement the success it deserves to be, as a gratifying compliment and acknowledgment of a very long period of valuable work.

## IRELAND.

MR. PASCAL P. LAW last week presented the Stewart Institution for Imbeciles with securities to the value of £3,105, for the purpose of building an additional wing to the Institution now being erected at Palmerstown. The thanks of the managing committee has been given to Mr. Law for his very handsome donation, and the warm interest he has always taken in the Institution.

## SMALL-POX IN DUBLIN.

WE regret to announce that the epidemic is most seriously increasing. Last week, we reported that there were forty-three small-pox patients in Cork Street Fever Hospital. This number is now almost doubled; there having been eighty cases of the disease under treatment in the hospital on Tuesday last. The largest number of cases in this hospital during the past fourteen years—a period which embraces the epidemics of 1864-5 and 1872-3—did not exceed the present number.

## SMALL-POX IN BELFAST.

A SERIOUS outbreak of small-pox has recently taken place in this town. On February 12th, a fatal case was registered, and, between that date and February 27th, twenty cases occurred, all of which were immediately removed to hospital, and every available means used to check the spread of the infection. At a meeting, last week, of the Guardians of Belfast Union, Dr. Reid requested the Board to make arrangements for increased accommodation for patients in the wards of the Workhouse Hospital; and it has been decided that, if parties continue to be admitted to hospital, more infirmaries should be opened in the workhouse, into which non-contagious cases could be transferred from hospital, in order that additional wards in the latter could be obtained. The disease has been traced to Ballymacarett, where small-pox prevailed some time ago.

## DEATH OF MR. HENRY M. JOHNSTON OF BELFAST.

THIS gentleman died on last Sunday morning, in his fifty-second year, at Bangor, where he had been temporarily residing. A few years since, a severe attack of illness occurred, which rendered his ultimate recovery hopeless, and he was necessarily obliged to give up all professional duties. By his medical brethren he was highly esteemed, and possessed the regard of many attached friends. His funeral was, according to his last wishes, a strictly private one, the remains being interred in the family burial-ground at Tullylish.

## FEES IN SANITARY PROSECUTIONS.

MR. DEELY, Sanitary Officer of Kilconnel District, recently applied to the Ballinasloe Board of Guardians for a fee of one guinea for giving evidence in a sanitary prosecution. The guardians declined to comply with the request, and obtained the opinion of the Local Government Board as to their liability in the matter. The reply of that Board was received last week, and was to the effect that, according to the terms of their Sanitary Orders of September 9th, 1874, paragraph 2, "executive duties", the sanitary officers are required to attend and assist in the proceedings in which their assistance may be required by the executive sanitary officers. The salaries allowed are, it appears, intended to cover those duties, as well as those specified in the previous parts of the order referred to.

## CORK DISTRICT LUNATIC ASYLUM.

At a meeting of the Governors of this Asylum held on the 1st inst., Dr. Lombard J. Tanner was elected Assistant Medical Superintendent in the vacancy caused by the resignation of Dr. Atkins. Lord Mountcashel proposed the following resolution, which was unanimously adopted: "That in receiving the resignation of Dr. Ringrose Atkins, on his promotion to the office of Resident Medical Superintendent at the Waterford Lunatic Asylum, this Board desires to express its high sense of the manner in which Dr. Atkins discharged his duties while connected with the institution; and though the Board with much regret parts with so valuable an officer, they rejoice on his own account that his merits have received so marked and advantageous a recognition." Dr. Eames, the medical superintendent, applied for an additional assistant, as the work of the Asylum was very heavy; it containing an average daily number of seven hundred and fifty-two inmates. Notice was given by one of the Governors to appoint a resident medical pupil under the terms of the fifty-second rule of the Privy Council.

## RATHFARNHAM WATER-SUPPLY.

THE guardians of the South Dublin Union last week, by a majority of votes, resolved to supply this town with the Vartry water. At present, the supply is insufficient, the water from the Rathfarnham pump being also extremely hard, and from an analysis of the city analyst it has been found that it contains sixty-seven and a half grains of solid matter per gallon, whilst Vartry water contains about four and a half grains.

## BELFAST ROYAL HOSPITAL.

THE usual quarterly meeting of the General Committee of this Institution was held last week. The report of the Board of Management for the past quarter stated that they had accepted from some medical gentlemen the portrait of the late Andrew Marshall, M.D., who was formerly one of the consulting surgeons to the hospital, and had placed it in the board-room of the Institution. Reference was made to the Convalescent Home, donations to which have already amounted to upwards of £6,000, and £500 in addition from Lady Johnston for furnishing same. It has now been completed, and is occupied by patients; but a further sum of £1,000 is still requisite to place the Home out of debt. Mr. S. Coates, senior resident surgeon, having resigned, has been succeeded by Mr. Jefferson, the junior resident surgeon, the vacancy thus occurring being filled up by the appointment of Dr. Henry O'Neill.

## THE SANITARY CONDITION OF CORK.

SOME time since, we referred to the inquiry instituted by Dr. MacCabe into the prevalence of enteric fever in this town; and, in reference to this subject, the recent report of the Cork Fever Hospital is interesting and instructive. It was proved, at the late investigation, that the sanitary state of Cork was capable of improvement in very important particulars; and from the evidence given, it could not be expected, in such a state of sanitation, the town could escape from periodical visitations of preventable disease. Dividing the nine years, from 1866 to 1875, into three periods, we find that, from 1866 to 1869, forty-six cases of typhoid fever were treated in the hospital; from 1869 to 1872, eighty-three were treated; and from 1872 to 1875, one hundred and thirty-one cases; making a total in the nine years of two hundred and sixty cases. The report points out that, although repeated analyses of the pipe-water have been satisfactory, yet this does not remove the responsibility resting on the sanitary authorities to free the river which supplies the reservoirs of all those impurities which should otherwise be disposed of; nor are we to be deceived by the disease not assuming, numerically, the character of an epidemic. The danger in the case of typhoid fever is the tendency to become endemic. The presence of the specific poison itself being primarily necessary, and the locality possessing the ingredients which favour its development and increase, the typhoid poison takes hold of the soil, it may be, or the water, remaining latent, and bursting out now and then with periodical vigour; and again, owing to circumstances of temperature or rainfall, retreating as it were for a period of rest. The greater the concentration of the poison, and the longer it is permitted to accumulate unchecked, the greater the virulence of subsequent outbreaks, and the further the penetration of the soil with the poisonous material. The characteristic relationship which exists between the prevalence of enteric fever and the rainfall does not appear to have held good in Cork. This relationship exists, and has been specially traced in certain cities where enteric fever is endemic, notably Basle, Berlin, and Munich. The evaporation from the surface, and the increased putrefactive processes with dry and warm weather, are supposed to account for this. The report adds that, when a competent and responsible superintendent medical officer of health is appointed for Cork, it may be hoped that all the various details of sanitary engineering, in which the town is now defective, will be entered into; and that, both as regards the source of the water-supply and the sewerage of the city, there may be no reasonable ground of complaint. The appointment of such an officer is the first step towards an improved hygiene; and we cannot too forcibly press the urgent necessity which exists for at once securing the independent services of a medical superintendent who is thoroughly acquainted with sanitary engineering.

## MEDICAL REFORM.

WE are informed that the Duke of Richmond will, in the course of a day or two, introduce into the House of Lords a Bill for the Amendment of the Medical Acts, having a tolerably wide scope. This Bill, which has been submitted to and altered by the Cabinet and will be introduced as a Government measure, has been officially laid before individuals, among whom are the members of the Executive Committee of the General Medical Council. It was so submitted, however, on the understanding that their opinion was requested officiously but not officially, but that they were not in a position to communicate the contents of the Bill to the General Medical Council at large, or to do more than offer their comments upon it with the view to assist the judgment of the Privy Council in the matter. Nothing, therefore, can be officially stated about the Bill until it has been introduced into the House of Lords by the Duke of Richmond. Opportunities will be given for its full consideration before it passes through its various stages.

We have reason to believe, however, that those will not be wrong who anticipate finding in the Government Bill—1. Provision for conjoint examining boards in the three kingdoms, with provision for the admission of women to examination by such conjoint boards; 2. Adequate provision for the amendment of the fortieth section of the Medical Act; and 3. Provision for the registration, under suitable regulations, to be made by the General Medical Council, of foreign and colonial degrees. To these will, we expect, be found added provisions for the education and registration of dentists and of midwives and obstetric nurses. As, however, the Bill has undergone modification since it was submitted to the Cabinet, the Government alone is responsible for the form in which it will be presented to the House of Lords. We fear it will be found to contain no provision for direct representation of the profession in the General Medical Council.

## THE RIGHT OF PRESCRIBING.

WE publish in another column a letter from Mr. Stanger of Nottingham, which relates to a matter of great importance. The case of the Apothecaries' Society v. Shepperly has, by the course of events, been transformed into a test-case by which the rights of the profession under the Apothecaries' Act will be decided. Previous decisions have already affirmed that the right of prescribing assumed by chemists in what is called counter-practice has no legal existence; and that this habit of counter-prescribing (largely carried on, to the great detriment of their patients and obvious danger of the poorer classes, and to the injury of a large section of the medical profession) is an infringement of the law. The actions in which these judgments have been obtained have been carried on nominally by the Apothecaries' Society; and it will be seen that in this case the Apothecaries' Society has not only contributed its name and authority to the conduct of the case, but has given a donation of £50 towards the expenses. Judgment has once already been given by an able County Court Judge in favour of the plaintiff; but, as is explained in Mr. Stanger's letter, the Judges of Appeal have sent the case back for re-trial, on the ground that the court which gave the judgment had not, in their opinion, sufficient material fully to decide all the questions in dispute. They have, moreover, removed the case from the County Court to the High Court of Justice, in order, probably, that the opportunity of appeal in the last resort to the House of Lords may be afforded to either party. The costs hitherto have fallen upon a small medical society in Nottingham, of which Mr. Stanger is the representative. It will, we believe, be very generally felt that the costs of a case intended to test the general rights of the profession ought not to fall upon a small section; and, as the question to be decided is one which concerns so large a body of the profession, the funds for prosecuting the case should be furnished by all who are interested in the subject. Directly or indirectly, the profession at large is concerned in it. Under these circumstances, Mr. Stanger's appeal is, we consider, founded on equity, and will, we anticipate, meet with a prompt, wide, and generous response from the members of the profession at large.

## THE ARMY MEDICAL DEPARTMENT.

THE following memorial has been forwarded to the Right Honourable Gathorne Hardy, M.P., Her Majesty's Secretary of State for War.

"The memorial of the President, Vice-President, and Council of the Royal College of Surgeons in Ireland humbly sheweth,—

"That your memorialists upon the 3rd of June, 1875, officially expressed to Her Majesty's Government their conviction that, unless active steps were taken to amend the condition of the Army Medical Department, 'serious public inconvenience would be felt in consequence of there being a deficiency of properly educated surgeons for the service of the army': a state of things which, your memorialists regret to learn, has come to pass.

"Your memorialists beg to state that, in pursuance of charters granted to them by Her Most Gracious Majesty and her royal predecessors, they have 'provided a sufficient number of properly educated surgeons for the army'; but your memorialists find that, with hardly an exception, these gentlemen will not take service in the Medical Department as at present organised.

"Your memorialists, therefore, feel that they would be deficient in their duty to the Crown and to the public were they not to call your attention to these facts, and again to urge Her Majesty's Government to take such measures as will tend to restore the Army Medical Service to its former position in professional estimation and public favour.

"ROBERT MACDONNELL, President, PHILIP CRAMPTON SMYLY, Vice-President, J. STANNUS HUGHES, Secretary, Royal College of Surgeons in Ireland.

"Dublin, March 5th, 1878."

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE annual meeting of this Society was held on Friday, March 1st. The President, Dr. WEST, took the chair at 8 P.M., and the ballot for the election of officers and Council for 1878-79 was immediately opened; Dr. C. Fish and Mr. E. Newton being nominated by the President as scrutineers.

*The Report of the President and Council* gave the usual details as to the numbers and position of the Society. These were of a favourable character. The deaths had been three below the average of many past years, and the new Fellows seven above the average, being respectively twelve and twenty-seven. The deaths comprised two honorary Fellows, five resident, and five non-resident Fellows; and the new Fellows, twenty-four resident and three non-resident. There had been an upward movement in the number of subscriptions from 258 to 265; and the total number of Fellows, honorary, resident, and non-resident, had risen from 651 to 665. The receipts exceeded those of the previous year by about £100; but, the year having commenced with a deficiency instead of the usual balance in hand, the available income was slightly less. The expenditure also was less; its details varying little from those of the previous year, with the exception of an excess of £50 expended on the library and a decrease in the cost of the *Transactions* of about £70. The balance in hand was £33 19s. 3d. The report then gave some details of the founding and settlement of the regulations of the Marshall Hall Memorial Prize, and stated that the Council recommended to the Society that the prize should be awarded to Dr. John Hughlings Jackson, for his investigations into the Pathology of the Nervous System. The Committee on Membranous Croup and Diphtheria were still engaged in sifting the material in hand, and their final report would not be long delayed. The Council recommended that a change should be made in the days of meeting. In the old arrangement, the meetings had been held from "November to June". In 1871, an alteration had been made to "October to May". It was now recommended that the meetings should be held from the fourth Tuesday in October to the second Tuesday in June.

The Honorary Librarians gave their annual report as to the increase of the library, the number of works added last year being 443; and they stated that the new catalogue and index were making progress through the press, and would probably be in the hands of the Fellows by the close of the year.

The adoption of the report (subject to a distinct motion on the paragraph relative to the alteration of the times of meeting, which involved an alteration in the by-laws), which was moved by Mr. CHARLES HAWKINS (who congratulated the meeting on the improvement in the financial condition over that of the previous year), and seconded by Dr. BUZZARD (who especially referred to his gratification at the excellent adjudication of the Marshall Hall Prize), was carried unanimously.

*Change of Days of Meeting.*—The alteration of the by-laws, relative to the proposed change in the days of meeting, was moved by Mr. COOPER FORSTER, and seconded by Mr. SPENCER WELLS. The Secretary, Dr. JOHN HARLEY, explained the reasons which had led the Council to adopt the recommendation in the report, among which were the injurious effects of too early a commencement of the session in lowering the number of members present at the first meetings, and the increase of the difficulty always felt by the Secretaries in obtaining papers for reading at that period. Mr. COOPER FORSTER, in moving the alteration, supplemented the Secretary's remarks by suggesting that some of the papers in excess at the end of a session might be held back to supply the probable deficiency at the beginning of the next. Mr. CURLING stated one objection to the change, in that it would again throw the consideration of some of the papers by the Council to a later period of the summer, when the Councils were not so well attended; and Mr. THOMAS SMITH referred to the small attendance at the June meetings, which, however, was replied to by the SECRETARY, who stated that, in making up the average, the numbers at the June meetings had been found to exceed those of the subsequent October ones. The motion was carried by a considerable majority.

*The Marshall Hall Prize.*—THE PRESIDENT then called upon Dr. Hughlings Jackson to receive the diploma of the Marshall Hall Prize, and addressed him as follows: "Dr. Hughlings Jackson,—I could have wished that, for this night at least, the chair might have been occupied by another than myself, so that you might have received your well-won honours from the hand of some one who had himself gathered laurels in the same field as you. But as this cannot be, I have at least the satisfaction of assuring you how much I am your debtor for the light you have thrown on my path in the daily practice of my profession; how often I have found your doubts worth more than many another man's assertions; how, even when I have hesitated to adopt your conclusions, it has been with the feeling that probably you were right and I was wrong, that your keener insight had shown you clearly facts the outline of which seemed to me still blurred and indistinct. Though all the Fellows acquiesce in the justice of the Council's award, it is yet perhaps fitting that I should mention the three chief grounds on which that award was made: 1. Your contribution to the increase of our knowledge of aphasia, and to the increased certainty of that wonderful discovery by which we are now enabled to localise the power of intelligent articulate speech in a certain district of the brain. 2. Your careful clinical observations on epilepsy, and the light you have thereby thrown on many points connected with the structure and functions of the brain. 3. Your researches with the ophthalmoscope, that instrument by means of which we see through the eyes as through windows to the brain. I hope, in time, we may arrive by its means at something approaching that certainty of diagnosis which auscultation has enabled us to attain in diseases of the chest. In handing you this diploma, which records your selection as the first Marshall Hall prizeman, I need not engage you to continue your investigations with the same diligence as heretofore, for 'the labour we delight in physics pain'; but do it with the same absence of self-seeking as has characterised your work hitherto, and you will continue to enjoy still the rare good fortune of praise without detraction, of honour without envy."

Dr. HUGHLINGS JACKSON, in receiving the diploma, made a reply, thanking the President and Society for the very high honour conferred upon him.

*President's Address.*—THE PRESIDENT then addressed the meeting, and after a few introductory remarks, entered upon his obituary notices of such Fellows as had been lost to the Society during the preceding year. The deaths were not so numerous as usual. Among them were five resident fellows: Mr. William Coulson, Dr. Thomas Heberden, Dr. Basham, Mr. Robert Dunn, and Dr. Cotton; five non-resident: Dr. Wm. Carr of Blackheath, Mr. Julian Jeffreys of Richmond, Mr. George Cooper of Brentford, Dr. Charles Mayo, and Dr. Frederick Davies; among the Honorary Fellows, the losses were Dr. William Stokes of Dublin, and Professor Claude Bernard of Paris.

The President concluded his address in the following words: "One thing has struck me much in drawing up these short notices of the deceased Fellows of our Society, that almost without exception they may be said, in words used long ago, to have 'served their own generation', not themselves. The sphere in which one worked was a wider, in which another a narrower one; this man threw his energies into the welfare of the parish where he lived; another devoted himself to the interests of the dwellers in the great continent of India; a third to the vindication of the principle which seemed to him to underlie the highest interests of our profession; while a fourth, not greedy of the gain which he might have had every day, nor thirsting for public distinction, helped the poor and taught the student almost to his dying day. I know that to praise the days that have fled, to live in the long retrospect rather

than in the short remaining future, is the natural disposition as life goes on and its sun declines. But for all that, I cannot refrain altogether from the question whether the spirit of the present day, the hurry to get on, the anxiety for wealth in order to meet a needlessly lavish expenditure, do not tend to emasculate the character by putting self, and that not a high self, in the place of something wider, nobler, better. Pardon me for raising the question here. Some may deem it out of place. It appears to me, however, that the first Medical Society in the kingdom should assert the highest principles in conduct, as well as the soundest in science; and strong in the strength which the position I owe to your kindness has given me, I have ventured to ask a question which of myself I dare not ask, which even now I crave your pardon for asking."

At the conclusion of the address, it was moved by Mr. J. MONCRIEFF ARNOTT, and seconded by Sir JAMES PAGET, and carried with great applause: "That this meeting expresses its best thanks to the President, Dr. Charles West, for his most excellent address; and that he be requested to allow it to be printed." Votes of thanks were also moved by Mr. GEORGE POLLOCK, and seconded by Mr. ERICHSEN, to the retiring Members of Council; and by Mr. CURLING, seconded by Mr. THOMAS SMITH, and carried with acclamation, to the retiring officers, Dr. John Harley and Mr. J. W. Hulke, Honorary Secretaries; and Dr. Charles Murchison and Mr. Timothy Holmes, Honorary Librarians; for their zealous and valuable services to the Society during the periods they had respectively held their offices. The two secretaries returned thanks; and on the motion of Dr. Harley, which was seconded by Sir JAMES PAGET, a vote of thanks was also given to Mr. Wheatley, the Assistant-Librarian. The scrutineers having returned from examining the lists, the President announced the result of the ballot for officers and council for 1878-9. The list of officers and council was given at page 309 of last week's JOURNAL.

#### ARMY MEDICAL DEPARTMENT.

THE following is a bare statement of certain grievances affecting the officers of the Army Medical Department, and of some of the causes tending to damage the efficiency of that Department.

1. Prejudicial abrogation, by Royal Warrant of April 1st, 1873, of the double organisation—staff and regimental—guaranteed by Royal Warrant of October 1st, 1858; and of its Clauses 1, 3, 4, 7, 17, and 21, upon the faith of which many medical officers were induced to enter the Department.

2. Sudden and totally uncompensated deprival, by Royal Warrant of April 1st, 1873, of regimental appointments, whereby many medical officers were caused considerable pecuniary and other losses.

3. Abrogation of Paragraph 1, Section 5, of the Army Medical Regulations of 1859 (relating to service on the West Coast of Africa), by Royal Warrants of 1866 and 1867, whereby serious damage has resulted in the case of at least one medical officer accepting these Regulations, as regards pay, promotion, and retirement.

4. Continued refusal of such terms of exchange as are freely allowed to all other officers of the army.

5. Continued refusal of such leave as is fully enjoyed by all other officers who, like the medical, are obliged\* to serve in all parts of the world: *a.* For due attention to private affairs; *b.* For professional study and improvement; *c.* For the recovery of lost health. One consequence of this latter deprivation is that the death-rate amongst army surgeons is twice that of other officers (*vide* Addendum).

6. Lowering the position of the senior executive medical officers by placing them on one common duty roster with the youngest juniors, and compelling them to perform such subordinate duties as hitherto have always been performed by the subalterns of the department.

7. The arbitrary, injurious, and prolonged deprivation of all means or opportunities of medical and surgical practice in the army; and, as a result of the existing ill-considered arrangements, many talented medical officers find it very difficult to keep pace with the continual and rapid progress of their profession.

8. The continued withholding, in certain instances, of the clerical assistance necessary to enable medical officers to comply satisfactorily with the rules by which they are required to have certain statistical returns, reports, and records prepared, furnished, and retained in safe custody.

9. Abrogation of the Royal Warrant of April 1st, 1873, by Regulations of 1876, depriving executive medical officers of the five years' tenure of regimental appointments guaranteed them by that Warrant.

\* British Army chaplains, commissariat officers, and storekeepers are not so obliged.

10. The seriously reduced and rapidly declining strength of the department (owing to a long-continued failure of candidates), leading to much and increasing overwork in the case of many medical officers.

11. A greatly diminished efficiency in the department, partly from the last-named causes, and otherwise by reason, not only of the prolonged absence of competition, but that also of the low standard of marks now accepted as merely qualifying for appointments in the Army Medical Department under the present ten years' system.

12. The wholesale supersession of many senior executive medical officers, of high character and professional ability, by the unexpected enactment of certain alleged rules, which were made to operate retrospectively, and which, if ever published at all in Great Britain or the colonies—which is doubtful—were certainly not communicated to those most concerned until, if ever, at any rate, a great many years after their entry into the department, on the strength of other and quite different rules.

13. Want of proper representation, protection, and sympathy towards the executive ranks by the administrative ranks of the department.

14. The worrying uncertainties of the position and prospects of army medical officers caused by the many breaches of agreement with them by the Government or its representatives during the last nineteen or twenty years.

ADDENDUM.—*Average Mortality amongst Army Medical Officers as compared with other Classes Civil and Military.*—The average annual death-rate per 1,000 of adult males in England is 9 to 10; Army officers, exclusive of medical officers, 15; Army medical officers from 1839 to 1854, 34; *a.* During Crimean war, 67; *b.* Since Crimean war, 20; Average death-rate of army medical officers during the last thirty years, 30. This increased death-rate does not take place among the older men, as in civil life, but the chief mortality is among the younger men of the department. The actual death-rate of the department is 44 per cent. greater than that of the males in civil life of all classes, and 75 per cent. greater than that of males of the same class as the army medical officers (including medical men) in civil life.

For the above data, *vide* paper by Dr. De Chaumont (now Professor of Hygiene at Netley) in the *Edinburgh Medical Journal* for November 1874, page 405.

## ASSOCIATION INTELLIGENCE.

### COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A SPECIAL MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday next, the 13th instant, at Two o'clock in the afternoon.

FRANCIS FOWKE,

*General Secretary.*

36, Great Queen Street, London, W.C., March 6th, 1878.

### SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT MEETINGS.

THE next meeting will be held at the Crystal Palace Hotel, Upper Norwood, on Thursday, March 14th, at 4 P.M.: R. M. MILLER, M.D., in the Chair.

The following papers are promised.

1. Mr. Golding Bird: The Treatment of Scrofulous Glands by the Electrolytic Cautey.

2. Dr. Poole: On the Non-Alcoholic Treatment of *Post Partum* Hæmorrhage.

3. Mr. Sidney Turner: A Case of Abdominal Tumour.

4. Mr. Sidney Turner: A Case of Opium Poisoning.

Dinner will be laid at 6 P.M. Charge, 6s. a head, exclusive of wine.

JOHN H. GALTON, M.D. Lond., *Honorary Secretary.*

Woodside, Anerley Road, S.E., February 26th, 1878.

### BATH AND BRISTOL BRANCH.

THE fourth ordinary meeting of the session will be held at the Museum and Library, at the top of Park Street, Bristol, on Wednesday evening, March 13th, at half-past 7 o'clock; H. MARSHALL, M.D., President.

The following papers are expected.

1. J. G. Swayne, M.D.: Case of Puerperal Convulsions.

2. W. H. Spencer, M.D.: The Use of Salicylic Acid in Combination with Opium and Aconite.

3. E. Markham Skerritt, M.D.: Cases illustrating the Treatment of Pleuritic Effusion.

4. A. E. A. Lawrence, M.D.: On certain Forms of Non-Puerperal Uterine Hæmorrhage.

A train leaves Bath at 6.35 P.M., and returns from Bristol at 10.15 P.M., Great Western Railway.

E. C. BOARD, } *Honorary Secretaries.*  
R. S. FOWLER, }

7, Caledonia Place, Clifton, March 6th, 1878.

### THAMES VALLEY BRANCH.

THE next general meeting will be held on March 14th, at the Griffin Hotel, Kingston, at 5 o'clock.

Papers will be read by—

1. Dr. Price Jones.

2. Mr. George Farr White: On Cerebro-spinal Meningitis.

3. Dr. Fenn: On Paroxysmal Hæmatinuria.

There will be a dinner at the above hotel at 7 o'clock. Charge, 7s. 6d., exclusive of wine.

Those members who intend to be present are requested to notify the same to the Honorary Secretary as soon as possible.

F. P. ATKINSON, M.D., *Honorary Secretary.*

Kingston-on-Thames, March 6th, 1878.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETING.

THE next meeting is appointed to be held at St. Bartholomew's Hospital, Rochester, on Tuesday, March 19th, at 4.30 P.M.: Dr. BURNS, R.N., in the Chair.

Dinner will be provided at the Bull Hotel, Rochester, at 6.15 P.M.

Papers have been promised by A. W. Nankivell, Esq., on Acute Necrosis; and by J. Thoresby Jones, Esq., on a Case of Displacement of the Sacrum.

FREDERICK JAMES BROWN, M.D., *Honorary Secretary.*

Rochester, March 5th, 1878.

### SOUTH-EASTERN BRANCH: WEST SURREY DISTRICT MEETINGS.

THE next meeting of the above District will take place at the Surrey County Hospital, Guildford, on March 21st, at 3.45 P.M.

Members wishing to read papers are requested to communicate with the Secretary at once.

There will be a dinner at the White Lion Hotel, at 6 P.M. Charge, 7s., exclusive of wine.

A. ARTHUR NAPPER, *Honorary Secretary.*

Cranleigh, February 26th, 1878.

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE next meeting of the above District will take place at the Harp Hotel, Dover, on March 21st, at 3 P.M.

Members wishing to read papers are requested to communicate with the Secretary at once.

There will be a dinner at the Harp Hotel, at 5 P.M. Charge, 6s. 6d., exclusive of wine.

WM. KNIGHT TREVES, *Honorary Secretary.*

Margate, March 2nd, 1878.

### YORKSHIRE BRANCH.

THE spring meeting of this Branch will be held at the Infirmary, Rotherham, on Wednesday, March 27th, at 3 P.M.

Members wishing to read papers or bring forward cases are requested at once to communicate with the Secretary.

After the meeting, the members will dine together at the Ship Hotel at 5 P.M. Tickets (exclusive of wine) 6s. 6d. each.

W. PROCTER, M.D., *Honorary Secretary.*

York, February 26th, 1878.

LEEDS.—Dr. Goldie states that the rate of mortality was rather high in this borough during the five weeks ending December 1st, especially amongst infants. Scarlet fever was still prevalent, but was much reduced by closing the schools in the infected districts; whilst small-pox was entirely absent from the death-returns. The uncertified deaths were 2.4 per cent. of the whole.

## CORRESPONDENCE.

## THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

SIR,—In reply to Dr. Grigg's last letter, I beg to state that I have decided to adhere to the statement made in my first letter; namely, not to publish any fuller report of the proceedings of the last meeting of the Committee of Council, until I receive instructions from the Committee to do so. I intend to call a meeting of the Committee of Council as soon as may be convenient to consider Dr. Grigg's letters, and he will then have an opportunity of submitting his objections to the Committee and explaining fully his views on their proceedings. I may be allowed to express my surprise that the secretary of so important a Branch of the Association as the Metropolitan Counties Branch should have failed to attend regularly the meetings of the Committee of Council, when he could not be unaware that matters of importance are frequently brought under its notice, and that the subject of acquiring premises for the publication of the JOURNAL has been for some time under the consideration of the Committee of Council, and no secret whatever has been made of their intentions.—I am, sir, yours, etc.,

R. WILBRAHAM FALCONER, M.D.,

Bath, March 6th, 1878. President of Council.

SIR,—As an old member of the Metropolitan Counties Branch, who has had some experience of the working of the Association during the last quarter of a century, I ask permission to make a very few remarks on the controversy raised by Dr. Grigg regarding the proceedings of the Committee of Council.

As to the publication of the minutes in the JOURNAL—a question which will be fully considered next week at a special meeting of the Committee of Council—I shall only remark that it has always been the practice to publish a selection from the minutes; and that the irksome task of making the selection has for some time past been laid upon the President of the Council, because the members of Committee, impatient to get away, will not remain, as they ought, to decide what portions shall be made public. After so bitter a personal attack as has, I regret to think, come from the secretary of my own Branch, I should imagine that Dr. Falconer and his successors will henceforth insist on the Committee of Council doing this difficult and often delicate piece of business itself.

But when I find Dr. Grigg lecturing the President and Committee of Council in the month of February on their misdeeds in regard to the new premises in the Strand, I ask where he was in October, when the subject was discussed in a full meeting of Committee, and every one who could make it convenient was requested to visit the premises and judge of their eligibility for himself? So much for the charge of secrecy brought against the Committee, and for the lynx-eyed vigilance of Dr. Grigg as a guardian of the pecuniary interests of the Association. I went, in common with others, to see the house, on the 10th of October; and while the general impression was that the situation was unexceptionable, some thought that the rent was high; and I am sure that every member of the Subcommittee specially appointed to look out for premises, of the Journal and Finance Committee, and of the Committee of Council, would have been heartily thankful to Dr. Grigg or any one else who could have put them in the way of securing so wonderful a bargain as that which Dr. Grigg now tantalises us with! Let him deplore in silence, if he will, the cruel fate that has prevented his conferring so great a benefit on the Association; but let him not hold up to the condemnation of their brethren those who were at their posts, and discharging their duties to the best of their information and ability.—Yours, etc.,

A. P. STEWART.

London, March 6th, 1878.

SIR,—I enclose, for publication in the JOURNAL, a copy of two resolutions which were passed without dissentient remark at the meeting of the Council of this Branch held on the 27th ult. They had been previously circulated amongst all the members of the Council. Letters were read from some influential members, who were unavoidably prevented from attending, expressing their warm approval.

A third resolution, which had also been previously circulated, would have passed, but, out of deference to Mrs. Garrett-Anderson as a lady, it was thought it would be better if the President had a personal inter-

view with her before proceeding to such an extreme measure as to request her to abstain from attendance at the meetings of the Association, where her presence was personally objectionable to several distinguished members of the Branch.—I have the honour to remain, etc.,

W. C. GRIGG, Honorary Secretary to the Metropolitan Counties Branch.

1. That this Council is of opinion that it is desirable that the Reports of the Proceedings of the Committee of Council should be published with as much fulness as is consistent with the conduct of business, and should in no case omit any important resolutions affecting the general interests of the Association.

2. That this Council desires to express its opinion that, in the selection of a central building and house for the Association, it is desirable that the meeting and committee rooms and central office should be separate from the printing and publishing offices.

## AN IMPORTANT APPEAL.

SIR,—I venture to make an appeal to the readers of the BRITISH MEDICAL JOURNAL on a matter in which I feel sure of obtaining their hearty sympathy, as it is one which seriously affects the interests of the whole medical profession. You have probably not forgotten the case of the Apothecaries' Society *v.* Shepperley, which was argued in the Exchequer Court during part of two days last November. It was an appeal from a judgment in the Nottingham County Court, by which a leading chemist and druggist in this town was fined in the full penalty of £20 for counter-prescribing. On the hearing of the appeal, several counsel were engaged, Sir Henry James leading for the appellant and Mr. Day, Q.C., for the respondents; but, after Sir Henry James had spoken for some hours, and before Mr. Day was heard, the Lord Chief Baron and Mr. Baron Cleasby, who were hearing the case, refused to give any judgment at all, and ordered that a new trial should be had, on the ground of the great importance of the case, and because, in their opinion, the court had not sufficient material before it fully to decide all the questions in dispute, especially the construction of Section 28 of the Apothecaries' Act, under which proceedings had been taken, a section which is somewhat ambiguously worded, and appears at first sight to exempt chemists and druggists from the penalties inflicted by the Act; and they directed that the case should be removed from the County Court to the High Court of Justice, in order, no doubt, that an opportunity of appealing in the last resort to the House of Lords might be afforded to either party. At the present time, the pleadings preparatory to the new trial are being delivered between the parties; but it is doubtful whether the plaintiffs will have sufficient funds at their disposal to justify them in going to trial, and it is quite possible that, at the last moment, the whole case will have to be abandoned. It is to prevent, if possible, so impotent a conclusion that I now venture to appeal to your readers. The nominal plaintiffs in the action are the Apothecaries' Society; that, as is well known, is rendered necessary by the Apothecaries' Act; and the Apothecaries' Society, when this case was commenced, gave it their sanction, and promised £50 towards the expenses: a sum which I need hardly say has already been considerably exceeded. The real plaintiffs are a society of medical men in this neighbourhood of whom I am the president, and, as our funds are not large, many of our members feel much reluctance to embark in a course of litigation which may very possibly not come to an end before the House of Lords has given its decision in the matter.

If it were, as at first we thought it would be, merely a matter in our own county court, or which at most would go no further than the court for hearing inferior court appeals, we should have considered it unworthy not to depend on our own resources; but, now that it has become a case of so much larger dimensions, and since we feel that its issue will affect the general interests of the profession just as much as those of our own particular society, we think we are justified in laying the matter before your readers, in order that they may have an opportunity of enabling this most important issue to be decided. The object of the trial, in short—or at any rate one of its objects—is to test in the most decisive and final manner the legality of counter-prescribing, and to define precisely the relative functions of chemists and druggists and medical men. That this object should be attained is to be desired both by medical men and by chemists and druggists; and, as the case on the other side has been taken up by the Chemists and Druggists' Association, so we hope that our side will receive the support of the general body of medical men. I shall be happy to supply any of your readers who may wish it with any further details respecting the case.

Contributions or promises of support may be sent to me; to the Honorary Secretary, Dr. Hatherly of Wellington Street, Nottingham; or, with your permission, to the office of the BRITISH MEDICAL JOURNAL.—I am, sir, your faithful servant, GEORGE EATON STANGER.  
North Circus Street, Nottingham, March 5th, 1878.

### THE LIVERPOOL MEDICAL INSTITUTION.

SIR,—My attention has been called to a paragraph in the JOURNAL of Saturday last, headed "The Midland Medical Institute", in which, after reference to the prospects of a building being erected in connection with that institute, the following statement occurs:—"Liverpool has failed for many years to obtain such an institute or library", etc. Now, the fact is that Liverpool has enjoyed for many years the advantages of a separate and independent medical institution: a building which was erected expressly for the purpose in the year 1837, at a cost of about £4,000; containing two theatres for holding meetings, a committee-room, large accommodation for a museum, and a library which, from the number and variety of its contents, will compare very favourably with other large medical libraries. The facilities afforded by the institution, which is the property of the members, are very great, and have been increased by recent alterations, the cost of which, over £600, has been defrayed partly out of the funds of the institution and partly by voluntary contributions. The institution now numbers one hundred and seventy-seven members; and its meetings, which are held fortnightly from October to May inclusive, are largely attended. On the occasion of the anniversary of the Association being held here in 1859, the meetings took place in the institution, which was found large enough to accommodate the members who were present.—I am, faithfully yours,

A. T. H. WATERS, M.D., President of the  
Liverpool Medical Institution.

Liverpool, March 5th, 1878.

### MATERIA MEDICA EXAMINATIONS.

SIR,—With all due deference to the views of Dr. Robert Farquharson on the above subject, I venture to think that the solution to them is to be found, not in lessening druggery to the medical student, but in endeavouring to make him more efficient by practical work. It is waste of time to lecture to students who have no knowledge of drugs practically. What knowledge can they get in a public hospital or dispensary? None, absolutely none; the very worst form of dispensing and the worst possible teaching. The only method is the pupil-system, either to a medical man in the country or a good chemist and druggist, for a limited time.

The *armamentarium* of the physician is the materia medica, just as the carpenter's tool-box is that of the surgeon. The man who knows the appearances, uses, properties, smell, and taste of drugs, and how they make up in combination, is the best physician; likewise, the man who can saw a plank without splintering, the best surgeon.

Having passed through a two years' pupilage with a botanical lecturer (where I also had the advantage of collecting all the specimens for the course), in which I made up every compound in the *Pharmacopæia*, gathered and made from fresh plants every drug (possible) that was to be used in medicine, I did not find, on going to a medical school, that my time had been wasted. On the contrary, I simply extended my knowledge *with ease*, and could laugh at the ignorance of those who prescribed *incompatible* mixtures. I need not weary you with the scores of such prescriptions I have seen from hospital experts; but two have lately come under my notice which I may mention. One is a mixture of diluted nitro-muriatic acid and prussic acid; I have been told it comes from Edinburgh. The other, I have been told, comes from Dublin; it is quinine mixture in a mineral acid solvent with Fowler's solution. I have not a London one in my memory just at present, but one could easily be found.

Pray, sir, will you be kind enough to tell me how young men are to learn that such drugs are incompatible, if they never learn practically the *Pharmacopæia*? If the youngster do not know the druggist's work, he certainly will never get credit for his prescriptions; and if he were to stand (invisible) behind the counter, he would hear what would make his ears tingle. As a pupil, I never lost an opportunity of going into a wholesale druggist's warehouse and looking at drugs in bulk. One or two months so spent would be of great benefit to every medical student.

I certainly cannot agree with Dr. Farquharson that a knowledge of adulteration of drugs is not essential; nor yet that the botanical characters of drugs are unimportant; a youngster thrown in a foreign clime can by the latter knowledge always find a substitute for the drug he

lacks, and he will find the former knowledge of paramount importance. No man can learn pharmacy out of a book, any more than he can learn anatomy; but he can learn the properties of drugs by trying them on himself or watching their effects on others. Perhaps the first is too much to expect, but it will teach caution.

I look on knowledge of the *Materia Medica* as the most important of all the studies a student has to learn, and least learned. It is the knowledge by which the druggist vies with the medical man and takes his bread out of his mouth; it is the knowledge which above all others should not be a sham; it is the knowledge which, combined with the rest of the medical student's curriculum, enables him to come down like a sledge-hammer on the quack; but let him lack this knowledge, and what is the use of his anatomy and the like in a case, say, of dyspepsia or troublesome cough? He knows not how to use and combine his drugs; the patient becomes disgusted and goes off to the druggist for medicine for "the wind" or "a cough", which should have been cured by his doctor. These are facts well known to every one.

With reference to Dr. Farquharson's remarks under "sixthly", I have only to say that the subject comes under the head of Toxicological Chemistry in the Forensic Medicine course, but I agree with him that it should be included in the *Materia Medica* examinations, and studied alongside with Practical Chemistry. A student well grounded in these essential details would learn his Anatomy and the rest twice as quickly as under the present system. It is true, Anatomy is very important, but *Materia Medica* is more important. Anatomy may ascertain for us where the dyspepsia or cough is situated, but it will not cure the cough or dyspepsia; and that is what our patients want, and our pockets.

For one, then, I sincerely trust that *Materia Medica* examinations, in the interest both of medical men themselves and their patients, will be made more searching and severe, and that a student shall know intimately every preparation and its incompatible in the *Pharmacopæia*.

—I am, sir, yours truly,

CHARLES MOORE JESSOP.

Clifton, March 2nd, 1878.

SIR,—That, after having spent much time in learning facts in materia medica, we all of us forget three-fourths of them, cannot be denied. But, when it becomes a question what shall in future be learned and what omitted, probably somewhat different views may be found to exist. For instance, I agree with Dr. Farquharson, that a student should not, with respect to any drug, be required "to furnish in writing any of the elaborate descriptive detail laid down in the *Pharmacopæia*"; but, on the other hand, if it be wished to make him thoroughly observant, he should be liable to be asked not merely the name of any drug or substance, but also how he knows its name; he should be asked, in fact, to describe it at sight, a feat which students, in common with most other people, have much more difficulty in performing than would be supposed prior to experience.

Dr. Farquharson, again, would give up the study of adulterations; but others would possibly regard that branch of the subject as very important under existing circumstances. A volunteer practical class, formed last summer for the purpose of experimenting on adulterations, proved, though quite an embryonic affair, the least unattractive part of the whole course. Indeed, I found that whatever could be seen or done was attractive and interesting to the students, but it was not always easy to interest them by mere lecturing, especially upon drugs strictly.

But the General Medical Council has suggested that we should teach nothing else than drugs, and that therapeutics should be taught by the lecturers on medicine. Now, it is true that first year's students have in some cases a surprising want of knowledge of simple facts in physiology, and, therefore, cannot appreciate remarks on therapeutics; but there is a very easy remedy for this. For its cause is as follows. Freshmen, often utterly ignorant even of such facts as might previously have been very easily gained in a month by the study of a dead animal or two, with the aid of a science primer, attend the same physiology class with second year's men. Before this intellectually heterogeneous mixture, a mass of details, experiments, arguments, and theories is necessarily placed for the benefit of the seniors. Bewildered by this multiplicity of details, now for the first time ever dreamt of, the freshmen realise nothing distinctly—they "cannot see the wood for the trees". But, now that science is beginning to be taught in schools, it is not too much to expect men to know something of physiology before they come to the schools of medicine. This should be added to the matriculation subjects. What would happen to an intending freshman at Cambridge who, proposing to study mathematics there, did not know beforehand something about triangles, circles, and other regular figures? Would he not be referred by the College authorities to his schoolmaster to learn from him the rudiments of his subject? But the medical schools

are the colleges of the medical students, and should have similar power to govern themselves in a matter of this kind, impelled as they very properly are by the examining boards to do their utmost in imparting real knowledge in what they may find to be the readiest way. But it is obvious that the colleges should agree among themselves to enforce a common rule—hence, it seems that the conclave of teachers of materia medica and therapeutics suggested by Dr Farquharson is eminently desirable from this point, as well as from some other points, of view—I am, sir, your obedient servant,  
T. CHURTON, M.D.  
Leeds, March 5th, 1878.

### THE LOST MEDICAL SCHOOL.

SIR,—In the *Life and Letters of Lord Macaulay*, I find, in a conversation between the late Prince Consort and Lord Macaulay in the year 1851, reference made to what they considered an efficient cause of the decadence of a great medical school. I am sorry to record that there is a monetary reason attached to it.

"I had a few words with the Prince about the Regius Professorship of Medicine. I remarked that it was impossible to make either Oxford or Cambridge a great medical school. He said, truly enough, that Oxford and Cambridge are larger towns than Heidelberg, and yet that Heidelberg is eminent as a place of medical education. There was hardly, he said, a physician in Germany, even at Berlin, even at Vienna, who made £1,000 a year by his profession. In that case, a professorship at Heidelberg may well be worth as much as the best practice in the great cities. Here, where Bright and Brodie make more than £10,000 a year, and where, if settled at Cambridge or Oxford, they probably could not make £1,500, there is no chance that the academic chairs will be filled by the heads of the profession"—I am, sir, yours,  
SAMUEL JACKSON.

Peel Cottage, Oldham, March 1878.

## MEDICO-PARLIAMENTARY.

*HOUSE OF LORDS—Thursday, February 28th, 1878.*

*The Medical Acts.*—The Duke of RICHMOND and GORDON gave notice that upon an early day he should call attention to the Medical Acts, and present a Bill upon the subject.

*HOUSE OF COMMONS—Thursday, February 28th, 1878.*

*The Factories and Workshops Bill.*—The House considered this Bill in Committee. On Clause 67, which forbids the appointment of any surgeon as certifying surgeon to any factory or workshop in which he is interested, Dr. WARD moved to insert after the word "workshop" the words "provided always that this shall not apply to the case of a person who is a shareholder in a public company". By passing the Clause as it stood, they would be doing a great injustice to the medical profession, for the terms were very wide.—Mr. CROSS could not accept the amendment. No alteration in the law was proposed, and no inconvenience had arisen from the restriction.—After some remarks from Mr. Gray, Mr. Gorst, and Mr. Macdonald, the amendment was withdrawn.—On Clause 68, making the regulation that certificates shall be given only at the factories or workshops where the children or young persons are employed, except where the number of children employed was less than ten, Dr. PLAYFAIR moved, as an amendment, that the word "ten" be omitted, in order to insert the word "five". His object was to secure, as far as possible, that the certifying surgeons should visit the factories and workshops for the purpose of examining children and young persons. As the law stood at present, it was only in cases where fewer than five children or young persons and children were employed that they were allowed to be examined at the surgeon's, and he wished that law to be maintained. Very strong evidence had been given against allowing children to be examined at the houses of the surgeons, as it tended in many cases to defeat the intentions of the legislature. He would also draw attention to the fact that, if the surgeon went to the factory, he got a small but reasonable fee—2s. 6d.; but, if the children went to his house, the small fee of 6d. was allowed in each case. Under Clause 87, a copy of the certificate might be given, and the clerk copying it would receive 1s.; and similarly, under Clause 97, if a copy of the certificate of birth was wanted, a fee of 1s. had to be paid the clerk; and yet the surgeon, who had to judge of the age, bodily health, and fitness of a person for a particular kind of work, was only to receive 6d. If he sent his horse to a veterinary surgeon, he had to pay a fee of 10s. 6d.; and if he sent his dog, he had to pay 5s. In the country, it might be only half this; but still, he thought, when they compared the payment of 2s. 6d. for the examination of a

dog with the payment of 6d. for a child, they would see that great injustice was done.—Mr. CROSS said he put in the word "ten" on the recommendation of the Royal Commission, and he thought there were some excellent grounds for adopting it. There was a great deal in what had been said about the desirability of children being examined at the factories, however, and he would, therefore, accept the amendment.—The amendment was, after discussion, agreed to; and the Clause as amended ordered to stand part of the Bill.—Mr. CROSS, in reply to Mr. Hopwood, said there was no appeal from the certifying surgeon's decision, except the general power of appeal to the Secretary of State which the Bill gave. He promised, however, to consider, before report, whether he could not introduce some provision in this respect.—On Clause 69, which provides that the fees to be charged by the certifying surgeons shall be as follows: 2s. 6d. for each visit, and 6d. for each person after the first five examined at that visit; a mileage fee at the rate of 6d. for every half mile completed over and above one mile from the surgeon's residence, and 6d. for every person examined when the examination is at the residence of the surgeon, Dr. CAMERON moved an amendment to the effect that the surgeon's fee should be 2s. 6d. for the visit, and 6d. for each person after the first examined at the visit. He said the amendment, if carried, would leave the remuneration of the surgeons as at present, inasmuch as in 1871 the inspectors of factories, on being appealed to, recommended that the maximum fee should be what he now proposed. The proposal of the Bill was to decrease that remuneration; and, as the tendency was for the wages of all classes to rise, he thought the surgeons had a good claim to be at least left in their present position.—Mr. CROSS said that under this Bill the certifying surgeons would receive many more fees than formerly; but, as before, he had no doubt that they would, as a rule, make their own agreement with the manufacturers. Whenever there was a vacancy for a surgeon, he received so many letters, addressed to him under the impression that he had the appointment, that he was induced to believe, from some cause or another, there was a great ambition among medical men to obtain these appointments.—Dr. PLAYFAIR urged that, as the Bill was professedly a consolidation Bill, it was inconsistent to make any alteration in the amount of fees to be paid to the surgeons. He quoted some figures showing the number of surgeons at present appointed, and the amount they were receiving, from which it appeared that there were 167 surgeons receiving from £50 to £500 a year (only two or three receiving the latter sum), and also that there were 445 surgeons who made less than £10, and not above £20 a year.—Mr. MUNDELLA objected to any increase in the fee, because such increase would fall upon the poor workers.—Dr. WARD was afraid that, if the Clause was passed as it now stood, the appointments would be filled by men of inferior qualifications.—Mr. CROSS said that no difficulty was experienced in obtaining the services of efficient men, who performed their duties in a most satisfactory manner.—Mr. GORST, Mr. HERMON, Mr. MUNTZ, Sir A. LUSK, and Mr. MACDONALD opposed the amendment, which was briefly supported by Dr. WARD, Dr. BRADY, and Mr. O'SHAUGHNESSY.—Mr. BIGGAR said that it was merely a doctor's question, and ought not to be considered when they were making laws for the whole community.—Dr. CAMERON denied that he proposed by his amendment to raise the fees at all. He should take the sense of the Committee upon it.—The Committee then divided: For the amendment, 54; against it, 223; majority, 169. The amendment was accordingly lost.—Sir A. LUSK moved that, when the examination was at a place more than a mile from the surgeon's residence, instead of "an additional sixpence for each complete half-mile over and above that mile" being lawful, that additional sixpence should only be chargeable for "each complete mile".—Mr. CROSS promised to consider the point; and the motion was withdrawn.—Dr. WARD moved that "shilling" be substituted for "sixpence". Practically, the sixpence was never taken, as surgeons would rather do the work for nothing than lower their professional status by taking so contemptible a fee. It was reducing them to something lower than the cabmen.—After some discussion, the amendment was withdrawn.—Mr. BIGGAR moved an amendment, the effect of which was that all surgeons who attended trials should receive a fee of ten shillings.—The SOLICITOR GENERAL explained that, if the medical man attended on being commanded, he would receive his fee under the law as it at present stood.—The amendment was negatived without a division.

*Army Clothing and Infectious Diseases.*—Mr. TORRENS asked the Secretary of State for War whether his attention had been called to the report of a Commission appointed by the *Lancet* to inquire into the risks attending the manufacture of clothing supplied to the army; and whether it was not urgent to take other and more effective measures than those at present adopted to detect and prevent the contamination of uniforms, etc., made for the British troops by workpeople who were

in contact or live with persons suffering from scarlet fever, small-pox, or other infectious diseases.—Mr. HARDY: On becoming acquainted with the article in the *Lancet*, the Surveyor-General of Ordnance inquired into the subject previous to the question being placed upon the paper; and, from his inquiries, I am bound to say there appears to be no ground for apprehension. Great care is taken that no infected clothing shall be given to the troops. I may mention that, among the people who have to do with the Clothing Depot at Pimlico, there has been only one case of small-pox known within five years; and in that case the patient, as he stated himself, had come from a neighbourhood in which the disease was raging. In conclusion, I may say that instructions have been given to the medical men to use every effort to prevent contamination.

Monday, March 4th.

*The Army Medical Service.*—In the course of his speech on the Army Estimates, Mr. GATHORNE HARDY said: I now come to the subject of the Medical Department. I feel I owe an apology to those honourable gentlemen who take an interest in this department for anything that may have fallen from me with respect to it to which they think exception might fairly be taken; but the worst I said was that it might lay itself open to criticism if, like a certain character in one of Dickens's novels, it continued to go on asking for more. The medical, I may add, is not the only department which does that, and I am far from wishing to throw any discredit upon it; though I adhere to the opinion that, in the case where there is not a horse to be kept, there cannot be a good claim for forage. The department has, at all events, done justice to the army, for the health of the troops has never, I believe, been better than during the last year, with the exception of those stations in the West Indies, where there have been some severe attacks of yellow fever. In the United Kingdom, the death-rate has not been higher than 8 per 1,000, while there has been no great amount of illness, there having been, I think, only 41 per 1,000 in hospital during the year. In India, the number in hospital has been 56 per 1,000, and the deaths have not been quite 14 per 1,000—a rate of mortality and disease which, I am sure, those who are acquainted with that country will not regard as very great. In the Mediterranean also, the health of the troops has been very good; and the most favourable accounts are given of the condition of those serving at the Cape of Good Hope up to the date of the very latest returns. It is supposed, it appears, from an answer which I gave to a question which was put to me in this House the other day, that I regard the condition of the Medical Department as being most unsatisfactory. I do certainly look upon it as unsatisfactory that there should be so many vacancies in the department; but I believe that in India, where the service is popular, the number of candidates very little exceeds the number of vacancies. I am told, indeed, that there is a very considerable reduction in the number of medical men altogether in proportion to the population, and that the demand for them in civil employment is very great. I have been assured by a member of this House that it is a common thing for a young man having £300 or £400 to buy a practice, and there is, no doubt, some difficulty in getting candidates for service in the army on the terms which we are able to give. The opening of the Civil Service and the competition for appointments in India tend very much to draw young men away from medical pursuits; but, be that as it may, the real state of the Army Medical Department on the 27th of February last was as follows. The number of executive medical officers on the Army List was 836. Six have since retired, leaving 830. To these must be added 25 surgeons, whose names have been sent in for the *Gazette*, and three surgeons who have come back from half-pay. Thus, the whole establishment for executive medical officers is, for 1877-78, 885, giving 27 vacancies. Nineteen candidates go to Netley on the 30th of March to meet these vacancies, so that there will be only eight vacancies unfilled. I cannot, therefore, say that the condition of the department is so bad as many seem to suppose. It is, however, at the same time quite clear that we must have medical men for the army. Our medical expenses this year are increased by the necessities of the Cape. I mentioned the other day that a good number of civilians had gone out to the Cape, inasmuch as it was impossible to obtain military medical officers to attend every detachment. We have done everything we could to make the labours of the medical men in the service less burdensome; and, although I have got a great many letters of complaint, I am quite unable to ascertain exactly what it is they want. There are, no doubt, those who wish to return to the regimental system. That system, however, has gone, and it would be impossible to recall it. It was put an end to in 1873, not only on the ground of argument, but of economy, and the certainty that in time of war it would break down at once. We must have all our hospitals on one plan and one basis, and it would be perfectly unfair, as to the roster for foreign service, that whoever happened

to be at the head of the department should not be in a position to give every man his fair turn of home and foreign duty, which can be done effectually under no other than the present system. I quite admit that system is on its trial; but the terms which I proposed were considered at the time by many medical men extremely favourable. The system may not answer, but I think it is entitled to receive a little longer trial. All that I have to add with regard to the whole subject is, that I have referred the questions of complaint to a very small Committee, having only one medical man upon it, and two others perfectly qualified to deal with them. They will formulate the complaints made on every point, and report to me with respect to such amendments as they may deem necessary in order to render the service more acceptable to medical men. I should be very desirous to make it so, because I feel there is no department in which it is more important to have efficient medical men than in the army, and that it is very bad when they happen to be dissatisfied with the service.—Dr. LUSH admitted that there appeared to be an indisposition among medical men to enter the army. He did not know to what cause that indisposition was attributable, but the fact was a very grave one, and he hoped the right honourable gentleman would continue to give the subject his best attention to discover if there was any grievance that could justly be complained of, in order that it might be remedied. The right honourable gentleman had fairly stated that the scheme he had introduced was yet on its trial, but he had no reason to believe that it would really be successful. He did not think there was any deficiency of persons entering the medical profession. Not long ago, a procession of three thousand medical students came down to the House; and one would have imagined that, with such warlike tendencies as had been attributed to them, there would have been no indisposition to join the army. In his own county, there had had recently been an election of a medical officer to the county asylum, when no fewer than fifty-six applications were made for the appointment. He hoped this question would receive careful attention, for it would be a most serious matter if our army should be undermined as regarded the medical staff.

*Public Health (Ireland) Bill.*—On the motion for going into Committee on this Bill, the ATTORNEY-GENERAL for IRELAND expressed his willingness to postpone further progress with the Bill for a fortnight; which, after a few remarks, was done.

## OBITUARY.

JAMES BLUNDELL, M.D.

On January 15th, Dr. James Blundell died at his house in Piccadilly, aged 87. He had retired from the practice of his profession for many years previous to his death, and was personally known to a comparatively limited number of the senior members of the medical profession. He studied medicine at the united schools of St. Thomas's and Guy's, under his uncle, Dr. Haighton, who was then lecturer on midwifery at Guy's Hospital. He afterwards studied at Edinburgh, where he eventually graduated in Medicine. On his return to London, he was associated at an early age as a teacher of midwifery with Dr. Haighton; and later, succeeded him in the chair of Midwifery. In his earlier days, Dr. Blundell devoted much time and energy to the study of physiology. His experiments went to show that the peritoneum could be subjected to surgical treatment without leading, as was generally supposed, to a fatal issue. He boldly advocated the operations of ovariotomy, and of laparotomy for the removal of the uterus and the relief of intussusception. He successfully removed the uterus in 1828, and the patient survived the operation for some months. The outcome of his earlier physiological studies was a volume of *Researches, Physiological and Pathological*, published in 1825. This work contains all the original investigations of Dr. Blundell on the subjects of ovariotomy and transfusion of the blood. He performed transfusion several times with success, and is justly looked upon as the father of the operation in this country. Three years later, his *Principles and Practice of Obstetric Medicine* appeared. It was still in the days when the custom of dedicating books to high personages was universal; and so the publishers of this work thought it would be an appropriate act to dedicate a book on midwifery to "Arthur, Duke of Wellington, the hero of a hundred fights".

If we may judge by the following extracts from his work on obstetric medicine, the students of his day must have been exceedingly clumsy, or of less than ordinary intelligence. What would a student of to-day say if he were advised thus? "Get the tape; and, after trying whether it is sufficiently strong, put it round the umbilical cord, and tie it very tightly (with a reefers knot) at the distance of an inch

or an inch and a half from the navel. Put another ligature on the cord, about an inch beyond the former, and cut between them. While doing this, you should put your hand between the scissors and the body of the child; for the latter is kicking about very vigorously, and one might cut off the penis by mistake. Such an accident as this the mother would never forgive; and the women would tell it from one to another till you lost all your practice." Again: "There is one other error which you may commit in using the short forceps. Most extravagant it is, and tremendous as extravagant! I mean the introducing of one blade into the rectum and the other into the vagina, the recto-vaginal septum becoming enclosed between the blade and the head. The error is possible, but is scarcely pardonable. The man who is guilty of such an enormity ought to relinquish the name of 'an accoucheur.'" At the same time, Dr. Blundell himself was certainly in advance of the obstetric practitioners of his day. He was in the habit of using the uterine sound to aid in the diagnosis between cystocele, inversion, polypus, and other uterine diseases.

His mode of lecturing was characterised by a careful attention to minute detail upon many points which now-a-days, in a midwifery course, pass unnoticed; yet entertaining withal. Speaking of the treatment of leucorrhœa, he says: "Women prefer colourless astringents; as Nature—with a view, I presume, of correcting the effects of the impurities peculiar to their sex—has given them the same fondness for cleanliness which we observe in kittens and other playful animals; and they do not like their dresses to be stained. The astringent which I generally use is alum; and it scarcely ever fails me. Our Saxon ancestors complained that the Danes stole away the hearts of their women by the fascinating custom of purifying their persons once every week. For aught I know to the contrary, many an accoucheur may have made his way to fortune by a commendable attention to the neatness of a shirt-plaiting! *Sic itur ad astra.*"

—In his mode of practice, Dr. Blundell was somewhat eccentric. We believe he was not in the habit of rising much before twelve o'clock. He would then receive patients at his own house till about six in the evening. Having dined, he would start on his rounds about eight or nine in the evening. He took with him in his yellowish chariot a lamp, by the light of which he would read one of a number of books which he always took with him. His rounds sometimes lasted several hours, and it was not uncommon for him to visit a patient in this way at as late an hour as midnight.

Dr. Blundell was well grounded in his youth in the classics, and in his later days he spent much of his leisure in the study of Greek. He had collected upwards of three hundred volumes of works on obstetrics and diseases of women. Many of them have the name of the late Dr. Orme written inside the cover. Some of them are rare and curious old books. Amongst others, there is a beautifully illustrated monograph on uterus bipartitus, entitled *Tabule quatuor uteri duplicis*, with Latin text. The whole of this interesting collection has been purchased by the Obstetrical Society of London from Dr. Blundell's executors for the sum of £20. He had also formed a collection of pathological specimens, which we believe the authorities of Gny's Hospital contemplate purchasing in a similar manner.

It is almost unnecessary to inform medical readers that the large fortune—nearly half a million—which Dr. Blundell left was not made in the exercise of his profession; it was bequeathed to him at different times. Although he early relinquished the practice of his profession, he did much, in conjunction with the late Dr. D. Davis, to elevate the department of obstetrics to a more scientific position.

**PRESENTATION TO MR. ROBERT THOMPSON.**—On Tuesday, February 28th, a very handsome bronze clock and pair of candelabra were presented to Mr. Robert Thompson, of Brandon, Suffolk, as a mark of esteem on his relinquishing practice. The clock bears the following inscription: "Presented to R. Thompson, Esq., upon his retirement from medical practice after a residence in Brandon of thirty-seven years, as a mark of respect and esteem by those patients and friends whose names are inscribed on the accompanying address." Along with the clock and candelabra, the following illuminated and richly framed address was presented: "Robert Thompson, Esq., Dear Sir,—We, the undersigned inhabitants of Brandon and its vicinity, feel we cannot allow you to retire into private life, after a residence of thirty-seven years as medical practitioner in Brandon, without some expression of our sincere esteem and regard. We, therefore, beg your acceptance of this address and the accompanying testimonial, consisting of a clock and pair of candelabra; and trust, by the blessing of God, both yourself and Mrs. Thompson may be spared for many years to enjoy that happiness and repose which your long and arduous professional labours so well deserve."

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, February 28th, 1878.

Appleton, Thomas Alfred, Cathcart Road, S.W.  
Atkinson, John Mitford, Winchester  
Davis, Arthur Randall, Langport, Somerset  
Pitt, Francis Dingley, Edward Street, Hampstead Road  
Wright, Harry Claude, Wynbery, Cape of Good Hope

The following gentlemen also on the same day passed their primary professional examination.

Curde, Charles, Charing Cross Hospital  
Hope, William More, University College  
Hughes, Thomas Montgomery, Charing Cross Hospital  
Hume, Walter Augustus, St. Bartholomew's Hospital  
Pegge, William Joseph, Manchester Hospital

## MEDICAL VACANCIES.

The following vacancies are announced:—

**BROMYARD UNION**, Parish of Cradley—Medical Officer and Public Vaccinator. Salary, £50 per annum, and fees. Applications to be made on or before the 6th instant.

**CLIFDEN UNION**—Medical Officer for the Clifden Dispensary District (Inishboffin). Salary, £90 per annum, exclusive of Registration and Vaccination Fees. Applications to the 13th instant.

**GORT UNION**—Medical Officer of Ardahan Dispensary District. Salary, £140 a year as Medical Officer, and £10 as Sanitary Officer, with Registration and Vaccination Fees. Election on the 14th instant.

**DUNFANAGHY UNION**, Donegal—Medical Officer of Gweedore Dispensary District. Salary, £100 per annum, with £10 as Sanitary Officer, exclusive of Registration and Vaccination Fees. There are also two Police Stations and a Coast Guard Station in the district, which are usually placed in charge of the Medical Officer. Applications to the 17th instant. Election takes place on the 22nd instant.

**MILLSTREET UNION**, Cork—Medical Officer of Workhouse, at a salary of £70 per annum. Applications, with Testimonials, to the 21st instant.

**NARBERTH UNION**—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.

**SLIGO UNION**—Medical Officer for Carney Dispensary District No. 2. Salary, £120 per annum as Medical Officer, and £20 per annum as Sanitary Officer, with the usual Registration and Vaccination Fees. Applications to the morning of the 13th instant.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

- \*BELLAMY, Edward, F.R.C.S., elected Surgeon to Charing Cross Hospital.
- CLIPPINGDALE, S. D., M.B., appointed House-Surgeon to the London Hospital, *vice* R. Atkinson, B.A., resigned.
- COOKE, Edward M., M.B., appointed Medical Superintendent of the Wiltshire County Asylum.
- CRADDOCK, F. H., B.A., M.R.C.S., appointed Senior Assistant Medical Officer and Deputy Superintendent of the Worcester County and City Asylum, at Powick, *vice* Edward M. Cooke, M.B.
- \*MACRELIGHT, W. W., M.D., appointed Consulting-Physician to the Torbay Infirmary.
- MARSH, E. A., L.R.C.P.Ed., appointed House-Surgeon to the Torbay Infirmary, *vice* J. B. Richardson, M.B., resigned.
- \*RICHARDSON, J. B., M.B., appointed Physician to the Torbay Infirmary, *vice* W. W. Macrelight, M.D., resigned.
- ROBERTSON, William Smith, M.B., appointed a Second Assistant Medical Officer to the County Asylum, Fareham, Hants, *vice* John Thomson, M.B., resigned.
- \*TAAFFE, R. G. B., M.D., appointed Consulting-Physician to the Sussex and Brighton Infirmary for Diseases of the Eye.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

### MARRIAGE.

**ROBERTSON—MAXWELL.**—At Rosehill Cottage, Hamilton, on the 5th instant, by the Rev. H. M. Hamilton, assisted by the Rev. M. P. Johnstone, \*R. T. C. Robertson, M.B., L.R.C.S.E., to Jessie, daughter of the late James Maxwell, Hamilton, N.B.

### DEATHS.

**SWAIN.**—At 20, Ker Street, Devonport, on February 26th, Harriet Eliza Cleeve, the wife of \*William Paul Swain, F.R.C.S.

\*WALLACE, Samuel, M.D., at his residence, Elderslie House, Cardiff, on January 21st, aged 51 years.

**PRESENTATION TO MR. J. B. RICHARDSON.**—Mr. J. B. Richardson has lately been presented with a testimonial on resigning the post of Senior House-Surgeon to the Torbay Hospital. The testimonial consisted of a handsome black marble time-piece, with the following inscription:—"Presented to J. B. Richardson, Esq., M.B., on his leaving the Torbay Hospital, by his patients, as a mark of their gratitude for his kindness and attention to them"; and also of a handsomely framed portrait of Professor Spence of Edinburgh, whose pupil Mr. Richardson formerly was.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Mr. Lund (of Manchester) will read a short paper, and show a patient from whom both Astragali were removed for severe Double Talipes; Mr. R. Davy will show cases in which he has subdivided the Tarsal Arch for confirmed Talipes; Mr. Adams will exhibit an improved Scarpa's Shoe for the Treatment of Talipes Equus Varus.

**TUESDAY.**—Royal Medical and Chirurgurgical Society, 8.30 P.M. Sir Henry Thompson, "Analysis of Five Hundred Cases of Operation for Stone in the Bladder of the Adult Male." The Calculi will be shown.

**WEDNESDAY.**—Hunterian Society, 7.30 P.M.: Council Meeting, 8 P.M.: Dr. Fletcher, "On the Diagnosis and Treatment of Idiocy, illustrated by Cases"; Mr. Jacobson will show a Child whose Tibia has been divided for Rickets.

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

DR. PROSSER JAMES ON LARYNGOSCOPY.

**SIR.**—If the person who uses the signature "A Student of Charing Cross" had read the preface of the second edition of my *Lessons in Laryngoscopy*, he would have found the following passage: "On returning to practice after a lengthened absence, occasioned by severe illness, I have not thought it necessary to revise the text of this little work. My attention has, therefore, been confined to the colouring of the new plates. These, I trust, will be found, if anything, an improvement on those in the former issue, on the accuracy of which I have often been congratulated."—I am, yours obediently,  
3, Dean Street, Park Lane, March 4th, 1878.

"MENSTRUATION."

**SIR.**—I keep pigs myself, and, though I cannot speak from actual experience, believe there is truth in the remarks of your correspondent "A Member" about hams going bad occasionally from the process of curing; with this difference, however, as to its cause, that if the *sows* are menstruating or "hogging," they should never be killed till a week afterwards. I have never heard that women who happen to be menstruating at the time they are helping to cure the hams would render the latter unfit for eating.—Yours, etc.,  
F.R.C.P.

**THE** following communications have been handed to the General Manager:—Mr. Anthony Temple, Kingston; Mr. Alfred P. Watkins, Worcester; Mr. Frederick Trevan, Port Isaac; Medicus, Newmarket; Mr. A. G. Macgregor, Canisbay, Caithness, N.B.

DIALYSED IRON.

**A MEMBER** of the British Medical Association requests the editor will have the goodness to say, in the answers to correspondents, what advantage the dialysed iron has over other oxides of the metal.

\*. Dialysed iron is alleged to have all the good effects of iron without producing constipation, disturbing digestion, or blackening the teeth. (See a notice in a previous page of the present number.)

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a Post Office.

LADY-MEMBERS OF THE ASSOCIATION.

**SIR.**—Surely the good sense of the Association can settle the question of the admission of lady-members without resorting to angry language or displaying passion. Such superfluities can effect nothing but injury to the Association. Societies in this country decide questions, however burning, by reasonable majorities, duly obtained and determined; and it is not to be doubted, in the settlement of this question, that whatever individual opinions may be, the voice of the majority will be accepted. All, therefore, required is, that the proper steps be taken to frame a law, which shall meet the wishes of the majority of the Association. Not many of our members will, I hope, approve the inconsiderate action or follow the lead of Dr. Wilson Fox and Mr. Lister—the one in resigning his membership, and the other in threatening to do so—because two ladies are members of the Association. These ladies have been members, we are told, for a period of five and three years respectively, and up to the annual meeting at Edinburgh their membership does not appear to have inflicted inconvenience or umbrage in the Association: in fact, it is probable that scarcely one member in ten up to that time was aware that we had ladies for our associates; and since that meeting, it seems that no one of those gentlemen who are so aggrieved by the presence of these associates have taken the proper and legal steps to prevent a recurrence of what they deem a great scandal—the admission of lady-members. I think most of your readers will agree with me, that it would have been time enough for Dr. Wilson Fox to resign, and Mr. Lister to threaten resignation, when a majority of members had decided in favour of the admission of female members. The world at large would reasonably say that only prejudice or passion could refuse to await the decision; and this resigning and threatening are the more surprising, because on the face of it they are quite unnecessary. The fact is before us, that three thousand out of (say) four thousand members have given their opinion against the admission of lady-members, thereby indicating pretty clearly what the vote of the majority will be when the question is placed before the Association for legal settlement. Moreover, I cannot believe that there will be found many members of the Association who will accept the advice given them as to dealing with the two ladies now members. These ladies were admitted in accordance with the laws of the Association, and, until better informed, I conclude that they cannot be legally ejected from the Association merely because they happen to be of the female sex, as has been suggested. Even if the ejection be legal, I am sure it would not be creditable to us. A new law may decide that ladies shall not in future be admitted, and would thus so far indicate that the admission of these two ladies was a mistake; but in this particular case, the mistake, supposing it to be one, was made by the Association, and those who make mistakes must themselves bear the burden of them as best as they may. The last thing they can honestly do is to inflict the punishment due to their own wrongdoing on those who are entirely innocent in the matter. To endeavour to expel these two ladies from the Association, or (as has been suggested) to write them a polite letter, enclosing their money-payments, and requesting them to take themselves out of it, seems to me, under the circumstances, a proceeding wholly unworthy of our great Association, and would for once justly render us obnoxious to some of those reprobations so often ignorantly and profusely dealt on our profession by outsiders. Surely we may anticipate that these ladies, knowing the feeling of the majority, will not ruffle the temper of members by their presence at Association meetings; and for the rest, as their membership does not appear hitherto for several years to have inflicted any other inconvenience on the Association, one would think (the principle of the non-admissibility of the female sex having been settled by vote) that eight thousand medical men might put up with the leave of two lady-members. And one more plea might be fairly added why a majority should be content not to drive things to their ultimate conclusion as regards these two ladies, and that is, that of four thousand (say) members who answered the question put to them, one thousand (say) replied in favour of the admission of lady-members. A reasonable majority, it should be remembered, always has the magnanimity of paying respect of some sort to a worthy minority.—Your obedient servant,  
W. O. MARSHAM.

London, March end, 1878.

**SIR.**—May I ask you to allow me space for a few lines in your valuable *JOURNAL*? As a member of the British Medical Association, I was present at the Discussion on Pleurisy at Manchester last year. As soon as a "medical woman" began to speak I rose, intending to go out. Some gentleman near to me said, "Sit down; don't you hear a lady is speaking?" Without venturing to give you the precise words of my answer, I may tell you that I did not sit down, but left the room at once. Apart from other overwhelming reasons why women should not be present at such meetings, there seems to be this powerful one, that no matter what she says, or who she is, the gentlemen present must sit and listen *ANXIOUSLY* to her—in other words, it would check healthy discussion. I may say that throughout the discussion members were constantly coming in and going out. Of course, it is needless to observe that the admission of these two "medical women" was totally irregular, as the rules do not specify properly qualified *men* as members.

I should not have ventured to address you on this subject, but that I am so pleased to see that the strong feelings of a humble individual like myself against the propriety of women practising medicine are only the same as those of my much respected teachers Sir William Jenner, Dr. Wilson Fox, and many other eminent members of the profession.—I am, sir, yours faithfully,  
Bradford, March 1878. EDWARD T. TIBBITS, M.D. LOND.

**SIR.**—Please remove my name from the list of the members of the British Medical Association. I am quite in accord with Dr. Wilson Fox as to the admission of females to the meetings of the Association, and would have earlier withdrawn my name had I been aware of the rules permitting their admission to the Association.

I hold that free discussion upon many subjects (surgical and medical) is impossible by men of refined feelings in the presence of females, who should be equally sensitive.—I am, my dear sir, yours very truly,  
J. F. WATSON.  
Heigham Hall, February 2nd, 1878.

DR. J. MASSEY (Nottingham).—Since the vote to which Dr. Massey refers, no women have been elected members of the British Medical Association. The vote was taken in 1876, and was taken in consequence of the fact that two ladies had previously been admitted members of the Association—one by the Council of the Metropolitan Counties Branch, and one by the Committee of Council. These ladies had, however, as has already been stated, been admitted before the vote, and none have been admitted since.

#### MEDICAL CERTIFICATES OF THE CAUSE OF DEATH, AND UNQUALIFIED ASSISTANTS.

SIR,—Will you kindly inform me, in your notices to correspondents, if an unqualified assistant having charge of a branch practice can legally sign death-certificates (not the registration form) for the principal? and if he can at present, will the new Medical Bill, should it pass, prohibit him?—Yours truly,  
X. Y.

\* \* It is undoubtedly illegal for unqualified medical assistants to fill up medical certificates of the cause of death and to sign thereto the name of their employer. Such a practice, however, supposing it to be sanctioned by the principal of the unqualified assistant, is not easily detected or prevented. Registrars are instructed that when they receive a medical certificate purporting to be signed by a registered medical practitioner, it is no part of their duty either to question the genuineness of the signature or to raise the question whether the deceased person had really been attended during his or her last illness by the practitioner whose name is appended to the certificate. It is evident that to sanction registrars to doubt the *bona fides* of certificates would seriously imperil the relations between registrars and medical practitioners. At the same time, we have reason to believe that very few unqualified assistants accept the grave responsibility of signing medical certificates with the names of their employers.

#### MEDICAL REFERENCES.

SIR,—In the JOURNAL for February 23rd, Mr. Pollard of Torquay brings under the notice of your readers the value of spirits of turpentine to *post partum* hemorrhage, as a remedy not generally known. In the *Medical Digest* of the New Sydenham Society will be found the following references:—*Medical Times and Gazette*, vol. ii, 1859, p. 342, Dr. Warren's specific; *Lancet*, vol. i, 1851, p. 303, Mr. Bradley reports one hundred and ninety-two cases, all successful; *Medical Times and Gazette*, vol. i, 1858, p. 143, Mr. Elliott states that since 1840 he has injected four ounces of turpentine as an enema, mixed with an equal quantity of cold salt water, and never knew it to fail.

Thinking the above notes may be interesting and useful to your readers, and illustrate the value of the *Digest* to every busy practitioner, for whose use it was specially compiled, I should feel obliged by their insertion.—Yours, etc.,  
February 1878.

RICHARD NEALE, M.D. Lond.

P.S.—In the same number, "A. M. D." expresses his surprise that calomel is not used in hydrophobia. Had he referred to Section 527, vol. v, of the *Digest*, he would have seen the value some practitioners entertained of this mineral in combating this disease.

#### A GROSS INSULT.

SIR,—When a man breaks into your house in the dark you call him a burglar, and when you meet him you may shoot him. The case is clear and the remedy decisive. But how stands the matter when the burglar attempts a breach in your moral sense, and what is the remedy? If indeed the offender intrude himself into your presence and convey his odious suggestions directly to your ears, you still have an easy remedy, and in its use may relieve to some extent, the injury done to your feelings; but when the moral burglar approaches you through the medium of a letter, and flings his filth from an obscure distance, how are we to cast it off and secure ourselves against a future attack? The enclosed letter, which has suggested the foregoing remarks, came to me by this morning's post; and in the interests of the profession which it dares to insult, I would—I was going to write "ask" you to publish it in its entirety, but the insult conveyed in the letter is too obvious and gross to need a request that you will permit me enough of your valuable space for this purpose.—I beg leave to remain, sir, very faithfully yours,  
Brook Street, Grosvenor Square, March 2nd, 1878.

JOHN HARLEY.

The letter enclosed is from an undertaker, and runs as follows:—"Dear Sir,—In returning the profession my sincere thanks for the liberal patronage and recommendations which I have received from them for the last ten years, I beg respectfully to intimate that, owing to my largely increasing business, in future instead of remitting cheques half-yearly, as hitherto, they will now be sent regularly every quarter. Furthermore, in reference to silk handkerchiefs, etc., I have made arrangements, when they are returned, in future to allow the full value of them, and place the same to the credit of the account. I would also here advise, when favouring me with your recommendations, that you will as soon after as possible send me your card, with name of deceased, so that there may be no mistake made in crediting you with the same. I also deem it necessary in recommending or sending servants, that you will warn them against making any mistake in the name and address, as there is another establishment within a few doors of me with which I have no connection whatever."

\* \* We have received many indignant protests against this insulting circular.

#### LOCUM TENENS.

SIR,—In reply to the letter of "M.D.," the agent is *not* liable to the principal for any act of dishonesty on the part of the *locum tenens*; neither is he liable to the *locum tenens* for salary which the principal declines to pay. The agent's duties consist merely in introducing to each other the two parties, using of course his discretion and every precaution to secure suitable and reliable gentlemen. The fee of 10s. (d.) is paid by the principal for the help provided for him, and by the *locum tenens* for the introduction to what is often a lucrative engagement; but no fee is paid by the *locum tenens* unless the engagement be for more than one week; and, moreover, the fee is uniform, however long the engagement lasts. The two cases quoted by M.D. are, as he must know, very rare; and when either arises it is all more rarely the fault of the agent.—Yours faithfully,  
A MEDICAL AGENT.

J. P. K. writes—Some time ago, the Obstetrical Society appointed a Committee to report on the means of recognising an Uterus which had borne Children. It was in connection with the Wainwright case. I have seen no report. Has one been published?

\* \* We will be glad to hear if the Committee has never met.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

CONSTANT READER (Nottingham).—1. Dr. Chambers's *Handbook of Diet*, published by Smith, Elder, and Co., will probably suit you best. Dr. Pavy has also published a valuable and elaborate work on the subject of diet. Some other practical hints are to be found in Dr. Dobell's book on the subject. 2. Diseases of the Skin: Tilbury Fox, Erasmus Wilson, and Livinge, choosing the larger or smaller handbooks as you prefer. 3. Morell Mackenzie and Lennox Browne.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Post; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Derbyshire Courier; The Auckland Times and Herald; The Auckland Chronicle; The Western Mercury; The Daily Courier; The Lincoln Gazette; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Masbrough Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Richmond and Ripon Chronicle; The Cambridge Independent; The Madras Mail; The Ashton Reporter; Saunders' News Letter; The Western Mail; The Bath Chronicle; The Bolton Chronicle; The Lincolnshire Chronicle; The Chippenham Chronicle; The Crewe Guardian; The West Sussex Gazette; The High Peak News; The Cardiff Times; etc.

\* \* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

#### COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. George Johnson, London; Dr. R. Shingleton Smith, Bristol; Mr. R. Clement Lucas, London; Dr. Lombe Athill, Dublin; Dr. J. Burdon Sanderson, London; Dr. H. Simpson, Manchester; Mr. A. E. Durham, London; Dr. A. B. Brabazon, Bath; Dr. Edis, London; Dr. G. H. Philipson, Newcastle-upon-Tyne; Dr. J. Milner Fothergill, London; Dr. Joseph Bell, Edinburgh; Mr. Eastes, London; Dr. J. W. Moore, Dublin; Dr. F. Warner, London; Dr. Bradbury, Cambridge; Dr. W. O. Markham, London; Dr. W. Fairlie Clarke, Southborough; Dr. G. de Gorrequer Griffith, London; Dr. J. MacGregor, Canisbay, Calcutta; Dr. Joseph Rogers, London; Mr. Wanklyn, London; Dr. Drysdale, London; Dr. R. J. Lee, London; etc.

# REMARKS ON PROVIDENT DISPENSARIES.

By TIMOTHY HOLMES, F.R.C.S. Eng.,  
Surgeon to St. George's Hospital, etc.\*

I HAVE been asked to open a discussion this evening on the subject of provident dispensaries in a paper which shall not take more than about twenty minutes to read, and which is intended more to elicit the various opinions and experience of those present, than to enforce any conclusions of my own; which, in fact, my acquaintance with the subject does not as yet qualify me to do.

We seem at last to be approaching a time when the reform, so long acknowledged to be necessary by most of those intimately acquainted with the working of our medical charities, will be taken seriously in hand both by the medical and lay public. This reform has been as yet advocated chiefly by medical men, though we have to acknowledge with gratitude the vigorous assistance given by a section of the laity, among whom Sir Charles Trevelyan and his coadjutors in the Charity Organisation Society are conspicuous. But it is clear that no real progress will be made until the conviction of the necessity of reform becomes general in the minds of the governing bodies of hospitals and other medical charities; and it is also clear, since no allegation is made of any flagrant abuse or corruption, and no demand is made for any sweeping or "sensational" change, that we cannot hope to excite the public mind by those picturesque declamations and stirring appeals to which they have now become accustomed, and wanting which their attention is apt to be but languid. We, on the contrary, being all of us sober men of business, and recognising fully, as we do, the many excellencies of our hospital system, are anxious that the changes which we believe to be necessary should be made after the fullest deliberation and discussion, and with such circumspection as will least endanger the other parts of a system of which we are proud and which many of us spend a great part of our lives in administering.

I think I need not take up much of your time this evening in enumerating the faults with which we charge the system of out-patient medical relief in the country in general and the metropolis in particular, or in the still more invidious task of proving those charges. The subject of this discussion is that of provident dispensaries, and I shall here assume that those present are convinced that our system of seeing out-patients is faulty in the following respects. 1. Admission is too indiscriminate, so that a number of persons are admitted beyond the powers of the institution adequately to deal with. 2. In consequence, it is impossible in those hospitals attached to medical schools to give that instruction which the students ought to derive from the out-patient practice. 3. Also as a consequence of this excess of numbers, the poor are made to wait an inordinate time for the advice given, and such advice, when obtained, is often hurried and worthless. 4. A great number of improper applicants are admitted; some who are better off than gratuitous patients should be; and a far greater number who are suffering from trivial maladies, the ordinary lot of humanity, which require no special skill for their cure, which are to be expected almost as surely as hunger and thirst, and which should equally be provided against as a part of necessary expenditure, reserving public charity for real emergencies.† 5. This

\* Read before the Metropolitan Counties Branch.

† The first conclusion arrived at by Sir William Fergusson's subcommittee was: "That a very large proportion of the out-patients of general hospitals (variously estimated at from *three-fifths* to *nine-tenths* of the whole) consists of *trivial cases* which do not require any special skill, and might be properly left in the hands of ordinary medical men. An inordinate number of trivial cases wastes the time of the consultee, wears the attention of the students, and fosters a habit of hasty diagnosis and careless observation, which tend to erroneous and ineffective treatment. In fact, out-patient work, as generally conducted, neither conduces to the sound advancement of professional knowledge, nor to the advantage either of the students or the public. And, bearing in mind that the staff consists exclusively of consultees, and that clinical teaching is one of the most important advantages derived by the public and the profession from the institution of public hospitals, the Subcommittee are of opinion that some special claim ought to be made out for perfectly gratuitous hospital advice, such as sudden emergency, surgical requirements, long-continued ineffective treatment, peculiar, obscure, and complicated disease, unforeseen and unavoidable distress, or some other special cause, making it desirable that the attention of a consultee should be given to the case. . . . As the hospital staff consists of consultees—not general practitioners—it is only consistent that their services should be asked for chiefly in cases of peculiar difficulty, prolonged anxiety, deep professional interest, etc.; and it is altogether unreasonable to call upon them to treat a case after case for many hours together, without, it may be, the occurrence of any single point of interest. . . . The Subcommittee, therefore, believe that the foundation of a series of

indiscriminate charity debauches and pauperises the persons to whom it is administered, and deprives medical men of a substantial part of the fund from which they are to draw their subsistence: an injustice and an injury both to the givers and receivers. 6. In attempting the impossible task of treating a vast number of affections, which really require rest and good hygiene more than anything else, by consultations and medicine given out at the hospital, positive harm is done to a great proportion of the patients, whose ailments are really thereby protracted. They get more harm from the exhaustion and crowd of the waiting-room and the exposure of the journey to and fro than they can possibly get good from the medicine supplied.\*

Assuming this, which I do merely to save time in the discussion, I am now to inquire how far the system of provident dispensaries seems calculated to remedy the evils complained of, and how far, in this metropolis and in the country, as far as my time allows me to treat that branch of the subject, it has really been successful.

I shall, I hope, be pardoned if, as an old hospital surgeon and teacher of surgery, I look on this matter mainly from the point of view of medical tuition. The chief motive, as far as I can understand, on the part of the medical officers of hospitals, for the retention of these overgrown out-patient departments, is that, out of the crowd of applicants, some "good cases", as they are technically termed, may be selected for treatment as in-patients. No one seriously contends that the time at the disposal of the out-patient physicians and surgeons is really sufficient to deal with all the cases they have to treat. I have never met with one of these officers who did not feel, as I felt myself when employed in that work, utterly dispirited and disgusted while struggling hopelessly to understand and give some rational advice and assistance to a crowd of trivial worthless cases, which, if they were worth dealing with at all by public charity, should have had the services of at least three times the number of consultants. Yet no one is more convinced than I am of the vital importance of selecting proper cases to occupy the beds of our hospitals, and especially those which are connected with medical schools, so as to supply the schools with the material necessary for efficient teaching; and I am most anxious that the medical profession should enlighten the public on this head. At present, it is too much the fashion for lay governors to pass over all matters connected with medical tuition as being merely technical, or as being the business of the doctors, not of themselves. The truth is that the function of hospitals in teaching medicine is a matter of equal, if not greater, importance to the public than their function in relieving a certain proportion (and let me say, in passing, only a small proportion, as far as in-patients go) of the sick of the community. Now, the out-patient department ought to be, and might easily be, as useful as the wards in teaching, and possibly even more useful. But its utility is in a great measure sacrificed to the supposed necessity of admitting a crowd of worthless routine cases.

In the first reaction caused by the increase of this crowd beyond all reasonable limits, attention was directed almost exclusively to the abuse of the out-patient department by persons able to pay for advice, and the only attempts made to reduce the numbers were by excluding those able to pay, *i.e.*, those earning more than a certain income. But it is clear that such a test is neither sufficient nor satisfactory. It is not sufficient; for, in our general hospitals at any rate, the exclusion of trivial cases is a far more important matter than the exclusion of well-to-do persons, who indeed are probably almost sufficiently deterred by the discomforts and fatigues of our overcrowded waiting-rooms. And the wages-test is highly unsatisfactory, unless the nature of the case is taken also into consideration; for it is obvious at once that a man earning forty shillings a week, but labouring under some very obstinate affection, or one requiring some special means of treatment, is a far more deserving, and a far more eligible, candidate for hospital relief than one earning thirty shillings a week, whose ailment is of a trivial nature.

Now, it is easy to imagine a state of things in which all this

provident dispensaries is a necessary condition of any improvement in the out-patient department of our public hospitals. The Law has, in their opinion, amply provided for the careless and improvident, and the funds contributed by the benevolent should be given in preference to the assistance of those who are inclined to help themselves.—Sir C. Trevelyan's pamphlet, p. 15.

\* Sir W. Gull said very happily at the meeting to which Sir C. Trevelyan's pamphlet was read: "Most of you know—I see many of the most eminent members of the medical profession present—that the poor have an idea that disease comes from Providence, and that it must be cured by drugs. Now, if there's an idea which ought to be rooted out, it is this. Children are often brought to be drugged when in reality they require to be washed and fed. I believe that one of the beneficial effects of our meeting here to-day will be that it will have a tendency to spread abroad the fact that disease should be prevented by attending to hygienic laws, by eating good food which has been properly cooked, by regulating the quantity and guaranteeing the quality of that which is taken."

might be put right; in which the hospital might regain its proper place as a consultative institution; might have out-patients in moderate number, whose cases would be available for the instruction of students; and in which provident dispensaries might take a very important share; whilst, at the same time, the complaints made against hospitals—both by medical men, as taking away from them much of their practice among the artisan class; and by economists, as pauperising the people—would be obviated. The leading principle of this change in the out-patient department would be this—that admission could only be obtained through some medical authority. The present methods of admission are extremely faulty. The unlimited admission of very poor persons, who come in out of the street, can hardly be described as otherwise than an absurdity. The haphazard admission of a limited number, though a great improvement on the former, yet does not insure any fitness in the cases admitted. Admission of out-patients by governors' letters is open to very grave objections; and, in fact, has been found to work so badly, that it has been given up in most of our general hospitals. The admission of out-patients by payment is liable to almost every objection which can be urged against all the other methods put together, besides many others which apply to it especially, and is besides utterly irreconcilable with the "charitable" character of our hospitals. But the admission for medical reasons, combined, of course, with a due regard to the patient's condition in life, is exactly in harmony with our usual method of admitting in-patients—where the letter of recommendation is supposed to guarantee the fitness of the patient's condition in life, and the preliminary inspection by the hospital physician or surgeon ascertains the medical fitness of his case. Now, if we had a perfect system of provident dispensaries, and if each of these was affiliated to one or other of the great hospitals of their district, it might be possible to carry out a regulation of this kind: That no person should be admitted—of course, this is exclusive of street accidents and of persons transferred from the wards to the out-patient room—as an out-patient, except on the recommendation of some medical authority residing in that district, be the medical authority a private practitioner, a provident dispensary, or a Poor-law dispensary. The numbers to be admitted daily might, as now, be limited; and of those admitted, some (I think a large proportion) might be admitted only for consultation, not for treatment. The medical man recommending the patient might join the consultation under certain regulations.

Some such scheme as this would insure a due supply of cases sufficiently grave to be worthy of charity, yet lying quite within the ordinary sphere of everyday practice, and in numbers proportioned to the opportunities of the institution.

Another method of connecting hospitals with provident dispensaries is that which has been adopted, and, as we learn by the Reports for 1875-6, successfully adopted, at the Royal Albert Hospital, Devonport; viz., to turn the out-patient department into a provident dispensary. Admirable as this method appears to be when applied to a country hospital, it seems quite unsuited to the circumstances of the metropolis—at least to those of our great hospitals connected with medical schools. The time allotted to me compels me to abstain from discussing the interesting question how far the smaller metropolitan hospitals might benefit, or the reverse, by conversion into provident dispensaries having beds attached.

But I am well aware that all this is as yet imaginary. Hitherto provident dispensaries have, in London at least, maintained a hard struggle for existence against the overwhelming competition of gratuitous institutions long established and of world-wide reputation.\* That they have maintained their existence at all testifies, we may hope, to a deep-rooted spirit of honesty and independence in a large portion at least of the poor of this city. That, if relieved from such competition, they would supply a widely felt want is proved by the experience of such institutions as the provident dispensaries at Torquay, Leicester, and Reading.

But, if we want the provident dispensaries to be relieved from such

\* The table on p. 104 of Sir C. Trevelyan's pamphlet on Metropolitan Medical Relief is the latest available list of Provident Dispensaries of the Metropolis to which I can refer. It shows only twenty-eight in the whole metropolitan police area, none of them in the immediate vicinity of any large hospital, except St. George's, where the out-patient department has during the last few years been restricted in numbers. At the general hospitals in the East and South of London, the numbers admitted were, according to the last published reports:

St. Bartholomew's Hospital . . . . .	137,313
London Hospital . . . . .	40,717
Metropolitan Free Hospital . . . . .	39,968
Guy's Hospital . . . . .	75,804
St. Thomas's Hospital . . . . .	61,524

355,631

the in-patients at the same hospitals in the same year (1875) having been only 21,370. No provident dispensary is possible in the districts under the influence of these institutions.—Sir C. Trevelyan, p. 13.

competition, it is necessary that we should found them on principles essentially just to the subscribers, the medical attendants, and the public, and with regulations which will harmonise with those of the great hospitals, and if possible increase, instead of impairing, the efficiency of those charities. It is our business to-day, as I take it, to see how far the provident dispensaries now in action meet these requirements.

In the first place, what is a provident dispensary? It should be, above all things, a public and permanent institution, having this, at any rate, in common with a sick club or benefit society, that it is supported by a regular fund, on which its members can rely as a guarantee that they will always find what they have paid for, with accounts duly audited and published, and managed by a public body, who can elect successors to the medical men as they resign. The private clubs which some practitioners establish, however meritorious they may be, have not these necessary elements of a provident dispensary, and have no right to the name; which, however, they sometimes assume.

Nor can I doubt that a very great advantage would be gained if it were found possible to consolidate all existing provident dispensaries into one great institution, the members of any branch of which should be admissible to any other branch on equal terms. (See Dr. West's speech on p. 126 of Sir C. Trevelyan's pamphlet.)

Another question—and it is a very serious one—is how this fund is to be created, whether partly by charity or entirely by the contributions of the members themselves. Opinions differ on this point. At present, in this city, there is, I believe, no institution, or at most one, unsupported by charitable contributions in aid; and few of those in the country are, I believe, entirely self-supporting. Probably, therefore, it is necessary to acquiesce in the arrangement suggested by the Charity Organisation Society (pamphlet, p. 73), that there must for the present be some charitable fund as well as the members' fund; yet many will agree with the spirit of Sir C. Trevelyan's note to the passage to which I refer,\* to the effect that such an arrangement should be only temporary, and that the scale of subscription should be so fixed as to make the dispensary in course of time self-supporting. Others will hold with Mr. Brudenell Carter (pamphlet, p. 122), that, as much of the illness under which the poorer classes suffer is due to the neglect of the public health on the part of the governing classes, it is only fair that the richer members of the community should help their poorer neighbours in this particular.

Another view of the matter is this: the better and more self-reliant part of the artisans are as anxious to maintain that manly spirit of independence which they possess, as any social reformer can be to infuse such a spirit into those who, unhappily for themselves, do not possess it. To these men the idea of belonging to a charitable institution is not agreeable. Much of the difficulty would be smoothed away if it were found practicable to adopt Sir C. Trevelyan's pregnant suggestion (*op. cit.*, note on p. 147) to appropriate to provident dispensaries "a portion of the vast unused or misused metropolitan charitable endowments". No poor man could, I think, object to send his child to a dispensary partly supported out of the benefactions of former ages, any more than a rich man does to take advantage for his child of the endowments of a school or university. The great City companies are now said to be intending to devote some of their large revenues to objects of immediate utility, such as technical education. Could not the members of this Association exercise some influence in obtaining a portion of these ample funds for the improvement of the present medical attendance on the poor of the metropolis?

Another and hardly less important detail is what is to be the qualification of members. The mere amount of wages is, of course, a fallacious standard;† and especially if combined with a fixed rate of contri-

\* "The time has arrived for adopting a simpler and stronger arrangement than the one here suggested. Any fixed apportionment between a 'Members' and 'Honorary Subscribers' fund, causes an imperfect appreciation of the real object to be kept in view—viz., that the honorary subscriptions should be merely of a temporary nature, and that the dispensary should become self-supporting at the earliest possible period. It also leads to the adoption of inadequate rates of contribution at the commencement which it is difficult afterwards to increase. The monthly payments should, from the first, be fixed so as to secure the independent position of the institution as soon as those families or individuals residing in the neighbourhood, who might reasonably be expected to join it, have become members, and the honorary subscriptions should be regarded merely as a provisional arrangement to tide over the transition period, until the dispensary can be fully organised. In other words, there should be only one fund based upon the members' payments, and the honorary subscriptions should be applied in aid of it as long as any are required."—C. E. T. May 1877.

† Possibly the rules suggested by the Hon. R. Capel at the Great Northern Hospital are as fair as any merely pecuniary standard can be.

"I drew up a scale in which I endeavoured to draw a line as to who were the proper persons to receive relief, those who should be referred to the poor-law, and those who should be referred to provident dispensaries. The real question to be solved is—Who are the people who ought to be gratuitously treated by our hospitals? In drawing up this scale, we said that the labourer who was in receipt of eighteen shillings a week, and single, was not the man who ought to receive medical

bution. Nor is it at all easy to fix in any case what the latter rate should be. The present rate of subscription is believed not to remunerate adequately the medical officers, as shown by an article in the *BRITISH MEDICAL JOURNAL*, January 1874; yet it could hardly be raised, at least in the case of the poorest members. Perhaps, as Mr. Nelson Hardy suggests in a note to me, it may be found possible to establish a sliding scale, as is done to some extent at the Battersea Provident Dispensary, where Class A, not earning more than 30s. a week, pay 1d.; and Class B, between 30s. and 50s., pay 2d. a week.

That a considerable fund might be raised for the remuneration of the medical officers of such institutions is shown by the fact stated in the first report of the Hospital Saturday Council, that, "on a moderate computation of the working population of London, a subscription of a halfpenny a week from the males, and of a halfpenny a month from the females, would produce £69,530". Now, at most provident dispensaries, the subscription is about twice this sum, and this would produce a fund which, I believe, would amply recompense the medical officers, and make the institutions independent of charitable support. But such an assumption would, of course, involve the absorption into the system of provident dispensaries of all the existing sick clubs; and it seems clear that, if the provident dispensary system do ultimately succeed in establishing itself firmly in the metropolis, the sick clubs might easily be amalgamated with them on equitable terms, one rate of subscription entitling the subscriber to medical attendance only, and a higher to an allowance also when sick.

There is another way in which I conceive that provident dispensaries, if affiliated to the schools of medicine, might be very valuable; I mean in giving our students that initiation into home practice which they used in old times to get during their period of apprenticeship, but which they now hardly get at all till they begin to have patients of their own. Some care would be necessary, of course, to see that the students were only employed in students' work, not, as used at any rate to be the case in some departments, in doing work nominally allotted to their seniors; but, with such regulation, the system would supply a want now widely felt in medical education.\*

Let me turn to another aspect of the question. We have been speaking of the benefits of these dispensaries, but we have met here also to hear the objections to them; for, as I said at starting, we are not enthusiasts, but sober men of business, fully alive to the benefits of the system we hope to improve, and fully convinced that no effort to found provident dispensaries can succeed unless all sides of the question have been carefully considered. The objections to provident dispensaries proceed from two sides. Those who will turn to the appendix to Sir C. Trevelyan's pamphlet will see a very interesting and curious collection of opinions on the scheme from a number of artisans of a high class, the printers in Messrs. Spottiswoode's office, containing the objections to it from their point of view. The main gist of these objections is, that the proposal is regarded as a movement on the part of the medical profession to restrict the benefits of the charity now extended to the working classes, for the purpose of putting money into their own pockets; as pressing hardly on the poor, who have already as many burdens as they can bear; and as tending to substitute

for the skilled attendance of hospital physicians and surgeons the inferior advice of young or unsuccessful practitioners. Now, it is of no use to deny that there is something in each of these objections. It looks, at first sight, hard to say "we mean to diminish the number of out-patients at the hospitals by about two-thirds, and we hope to raise a fund of some £140,000 a year from the working classes, which is to go, in a great measure, into the pockets of medical men". But let us remember that the proposal rests on the assumption (which we think we can prove) that the two-thirds relief of which we intend to deprive the working classes, is not only worthless in itself, but impairs the efficacy of the other third; also that the attendance which will be given in consideration of the payment required, is that which hospital out-patient departments neither do nor can supply, and which it would be impossible to have provided gratuitously; viz., the domiciliary treatment of all the poor in the metropolis on reasonable terms by experienced medical men: a benefit almost necessarily involving the improvement of the dwellings and other conditions of life of the patient.\* That the necessary funds could be contributed without any difficulty by the persons interested, is the opinion of almost everybody who knows the circumstances of London artisans; nay, it is probable that the expenditure would repay itself in the saving of time, the shortening of sickness, and the improvement of general health. Nor would the extra expenditure be at all equal to the gross total of the fund. Much of the assumed £140,000 a year is already spent on medical attendance in other ways, and would be simply transferred.

As to the qualifications of the medical officers, that is a matter which ought to be in the hands of the members or managers of the dispensaries themselves. If the pay be adequate, plenty of skilled candidates will be forthcoming; and the rules of election should be so contrived as to insure an intelligent choice. Nor have the advocates of the scheme the least wish to curtail the benefits really extended at present to the working classes by our hospitals. Far from this, they wish to increase them. Only the real benefit they believe is by no means measured by the number of persons seen. It is obvious that, to give deliberate advice and treatment to one person is a greater benefit than to hurry over three cases, none of which is, or can be, properly attended to.

I may mention that Sir C. Trevelyan has put into my hands two little tracts, one styled *Doctor's Bill and No Doctor's Bill*, published by the Ladies' Sanitary Association, and the other *Provident Knowledge Papers*, published by the Provident Knowledge Society, which put the claims and advantages of provident dispensaries in clear, familiar, and sensible language, and in a style adapted to those for whom they are intended. In this meeting, however, we are probably more likely to hear the objections to the scheme made by medical men; and the full discussion of such objections will much enlighten and assist those who advocate it. It is, perhaps, hardly my province to anticipate what will no doubt be urged with more force and fuller knowledge by others; for I hope the meeting will be attended by gentlemen who are, or have been, actually engaged in working these dispensaries, and who can tell us their weak points. My object in this meeting will be fully attained if it elicit any general assent to the view which I have long held with regard to out-patients of hospitals, that none should be seen gratuitously except for special reasons guaranteed by some medical opinion, and that the out-patient department of a hospital should be a consultative department for the institutions and practitioners who treat the poor of the district.

I have endeavoured to restrict myself within the narrowest limits of space, content if I can indicate the chief points on which the discussion may, I think, usefully proceed.

relief from the hospital, and was to be referred to the provident dispensary; that the married man, with slightly higher wages, ought also to be so referred; and that the married man with twenty-six shillings a week, no matter how many children he might have, should depend upon the provident dispensary for his medical assistance."—Sir C. Trevelyan's pamphlet, p. 128.

\* The following is from Sir William Fergusson's Subcommittee on General Hospitals:—"One of the most glaring defects in the present system of medical education—a defect which has become more and more prominent since the discontinuance of the system of apprenticeship—is the entire absence of practical acquaintance with the domiciliary treatment of disease. In the hospital, everything is at hand—the formula for the prescription, the nurse with every convenience, the dietary fixed and suitable, and the ward with perfect cleanliness and space—whereas even in the most perfect private dwelling the medical attendant is called upon to tax his ingenuity and resources to the utmost. He must give instruction as to ventilation, cleanliness, feeding, nursing, etc., and these and other directions have to be varied in almost every dwelling. He must also write out to full his prescription, so that it may be clearly understood. The Subcommittee are, therefore, of opinion that the teaching power of the out-patient department would be very largely increased if students of three years' standing were required to attend for six months as assistants at a provident or Poor-law dispensary; and they think that some provision might be made by which serious and interesting cases admitted to these institutions shall, through the instrumentality of the dispensary, be transferred to the hospital for special treatment and clinical illustration. By such an arrangement, the consulting staff of hospitals would at all times be able to secure the attendance at the hospital of a series of cases illustrating special diseases, and by this means also carry out and test special modes of treatment; whilst, as in Edinburgh, the affiliation of such dispensaries to hospitals would always secure the prompt admission of acute diseases and of cases requiring the peculiar resources of the hospital. It is believed that an ample field of useful and interesting observation would always be secured to the out-patient staff, without the possibility of abuse, and they therefore think that the out-patient department ought to be recognised for purposes of special clinical teaching in the same way as the in-patient department is already."—Sir C. Trevelyan, note to p. 29.

\* "The slender resources of a working man are soon broken down by 'doctors' bills', but there are few who cannot afford a small continuous payment made from month to month on the principle of mutual assurance. For this each family obtains, not as an act of charity, but by right, medical attendance and medicines at their district dispensary, or, it need be, at their own home; and they also have the privilege of selecting their own medical attendant from among the officers of the dispensary. Not the least advantage of this system is that the homes of the people are brought by it into just prominence. Much has been said of late years about the salutary influence of a trained nurse upon a working-class ménage. The practised eye of a well instructed medical officer from the district provident dispensary, in the numerous cases better treated at home than in any institution, would not be less efficacious, and, besides giving useful support to the nurse, would much promote the object we all have at heart, of providing improved dwellings for the working-class."—Sir C. Trevelyan's pamphlet, p. 17.

LINCOLN URBAN.—There were 1,286 births and 670 deaths registered in this city during 1877. The death-rate is estimated at 22 per 1,000, and, exclusive of deaths in public institutions, only 19. There were 14 deaths from typhoid fever, and 8 from scarlet fever, as well as several from whooping-cough and diarrhoea. About 25 per cent. of the deaths were caused by diseases of the respiratory organs.

## ON INTERNAL URETHROTOMY BY AID OF A NEW URETHROTOME.\*

By ARTHUR E. DURIAM, F.R.C.S. Eng.,  
Surgeon to Guy's Hospital, etc.

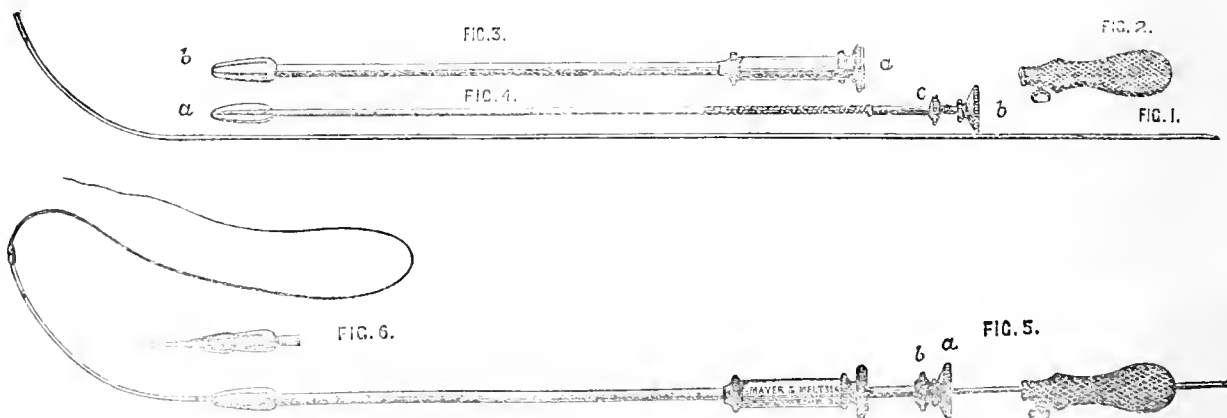

I do not propose on the present occasion to discuss in full the general merits and demerits of the operation of internal urethrotomy, nor to comment upon and criticise the published opinions and experience of the many distinguished surgeons who have hitherto praised or condemned this operation; still less do I propose to discuss in detail the comparative advantages and disadvantages of the several methods and instruments that have been from time to time devised and recommended for its performance.

I wish rather, in the first place, to indicate the circumstances and considerations that have led me to make trial of the operation of internal urethrotomy, and to the belief that this operation will probably prove to be a safer and more permanently successful method of treatment in exceptional, if not in ordinary, cases of urethral stricture than, so far as I know, is at present commonly supposed and represented. Further, I wish to submit to the meeting the instrument I have devised, and the method I have adopted, and to point out and illustrate, so far as I may be able, what appear to me to be their especial merits and advantages. And, lastly, I propose very briefly to state the results of my experience hitherto, however limited and imperfect, and therefore inconclusive, such experience must be considered to be.

Although, however, my experience of internal urethrotomy is at present limited to but few cases, I may venture, without undue assumption, to assert that my experience in the treatment of stricture of the urethra has been both considerable and extensive: considerable in regard to the number of cases, and extensive in regard to the variety of forms and complications presented, and the methods adopted for giving relief. In common, I believe, with every surgeon of experience, I have become more and more impressed by the want of permanence in the success obtained by the ordinary methods of treatment of stricture of the urethra, however great and striking may have been the relief temporarily afforded; and, from time to time, with increased opportunities, I have met with an increased number of cases in which the ordinary methods have been either altogether inapplicable, or at best have proved ineffectual in affording any satisfactory measure of even temporary relief.

my care in which internal urethrotomy had been previously practised, but in which I am convinced equally good (if not better and more permanently good) results might have been easily obtained by ordinary methods of dilatation. And I have at the present time under treatment one of the most difficult cases of stricture I have ever had to do with, in which it seems to me manifest that the obvious tortuosity of the existing passage is due to the effect of an internal urethrotomy performed some time since. It seemed to me that what was wanting was some method by which the natural passage should be restored, and the stricture-substance (if I may use such a term) got rid of by absorption or otherwise, rather than a method by which a new passage should be made above or below the strictured part. With the view of supplying such method, I devised the instrument which I now venture to bring before you. It has gone through several modifications suggested by experience in its use, and I do not for one moment pretend that it has yet reached anything like perfection; but I cannot help believing that the principles involved in its construction and application are worthy, at any rate, of consideration and more extended trial than has yet been made of it.\*

The instrument consists, in the first place, of a slender steel guide curved in catheter form. (Fig. 1.) This is hollow, and either open at the extremity, for adaptation by screw to a filiform whalebone bougie previously passed after the method of Otis and others, or else closed and rounded at the extremity with openings like those of a catheter for the indicative escape of urine. This guide has four longitudinal grooves (too fine to be represented in the figure) throughout the extent of the straight portion. To facilitate the manipulation of the guide, a small ebony handle (Fig. 2) is slid on to it and fixed by a screw. When the guide has been introduced through the stricture and the bladder has been reached, as evidenced by the escape of urine or otherwise, the handle is removed, and the main part of the instrument is slid on. This consists of a tube (Fig. 3) having a hollow cylindrical handle at the proximal extremity (a), and at the distal extremity an elongated slightly tapering olive bulb in which are four slits (b). Sliding within this tube is a second (Fig. 4), somewhat longer, and furnished at the distal extremity with four sharp-pointed sharp-edged blades (a); its proximal extremity is expanded into a circular flat plate (b), between which and the top of the handle of the outer tube is an adjusting screw (c); when this adjusting screw is down on the top of the handle, the blades are securely fixed within the olive bulb of the outer tube, and in this state the instrument is slid down upon the guide until the stricture is reached. The whole instrument put together is shown in

Such being the case, I have often considered the question of internal urethrotomy. But, without doubting or wishing to dispute the excellent results recorded by others, I have been deterred until recently from adopting the operation, because none of the methods with which I was acquainted commended themselves satisfactorily to my judgment. In this I may have been mistaken; but it appeared to me that, in many of the successful recorded cases, simpler and less hazardous methods might have proved equally efficacious, and, still more emphatically, that the various instruments devised were either wanting in precision and accuracy of application, or else that they served to cut a fresh way by the stricture into the urethra beyond rather than effectually to operate upon the strictured part itself. I have had cases under

Fig. 5, with the filiform conductor attached: a is the plate of the inner tube, pressure upon which causes projection of the blades; b the adjusting screw. The bulb being then firmly applied to the face of the stricture, the adjusting screw is turned up so far as may be deemed desirable. Pressure upon the top plate of the inner tube will then cause projection of the blades through the slits in the bulb (Fig. 6), and the strictured part of the urethra will be cut to a slight depth at four points in its circumference. Removal of the pressure is followed by withdrawal of the blades within the bulb by spring action (the spring being in the cylindrical handle of the outer tube). The bulb is then pushed on. If the stricture have been divided to a sufficient extent, the bulb will pass freely on. If it should still be arrested, another and another

\* Read before the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

\* I am much indebted to Messrs. Mayer and Meltzer for the pains they have taken in carrying out my suggestions.

projection of the blades may be necessary, and can, of course, be easily accomplished. Such projection of the blades is repeated until it is manifest that the strictured part has been sufficiently divided, and the bulb can glide on beyond it. The instrument is then withdrawn and a full-sized catheter at once introduced.

The advantages which this instrument seems to me to offer are these:

1. The facility and safety with which it may be used, and the accuracy and precision with which it may be made to act upon the strictured part of the urethra and no other.

2. The exactly limited depth to which the incisions extend. They can scarcely be made to a greater depth than what corresponds to the proper circumferential extent of the urethra.

3. Four incisions of slight depth into the stricture-substance (if I may use such a term as I have said), are made instead of one incision of comparatively great depth, as with the ordinary instruments, and which may, and probably often does, extend considerably beyond the stricture-substance into healthy tissue. Thus the stricture-substance is more effectually treated, and the healthy tissues have better chance of escape. And here I would point out that the effect of incising the cartilaginous hard stricture-substance may be not inaccurately compared to the effect familiar to all surgeons produced by notching or incising the thick callous edges of certain old external ulcers. In this latter case, we see how speedily new action is set up, and how the indolent indurating material disappears and a healthy healing process is started and established. May it not probably be the same with the stricture-substance?

4. The stretching and dilatation of the previously strictured part is obviously rendered more uniform.

5. And, lastly, the healing or cicatrising process is facilitated, inasmuch as the extent of cut margin from which cicatrization can go on is necessarily greater in the case of four shallow cuts than it would be in the case of one cut made so deep as to allow of equal dilatation of the passage.

Having thus described the instrument I have devised, and indicated what appear to me to be its advantages, I pass on to state the results of my experience of its use; and, very limited although such experience has at present been, the results have been such as to encourage me to persevere in its use in any seemingly appropriate cases that may come before me. Hitherto I have only had what seemed to me legitimate occasion for resorting to this method of treatment in twelve cases, but in all of these the results have been so far most satisfactory. To two of these cases I would especially ask attention, inasmuch as in them a degree of success was easily and speedily obtained far beyond anything that could have been expected to have been attained with equal ease and speed by any other method with which I am acquainted.

In none of the cases was there any hæmorrhage worthy of note. I have often seen more follow attempts at catheterism. In one case only was there anything like severe constitutional disturbance; but the patient in this case was a man of very intemperate habits; the symptoms from which he suffered more resembled those of a slight attack of delirium tremens than those of traumatic delirium; he had but one rigor, and his temperature was only over 100 deg. on one day. In one case only was severe pain complained of after the operation; but in this case I am inclined to believe that the pain was due to the fact that I had introduced and left in a catheter of too large size (No. 12). In no instance was there any indication of extravasation of urine or of perineal abscess. In all cases, when last seen, the patients were able to pass urine in full stream, and a large sized catheter (10 or 12) could be introduced without hitch or hindrance. In all instances, the progress was more rapid, and the satisfactory result was obtained with less confinement to bed than, so far as I can judge, would have been the case if the ordinary treatment by gradual dilatation had been adopted, even supposing that such treatment had been applicable. In all cases except one, a catheter changed from time to time was fixed in for some days after the operation, the number of days varying according to the conditions and indications of the case. In the one exceptional case alluded to, the patient himself pulled the catheter out during the night after the operation. I thought the opportunity a good one for testing the desirability of dispensing with the retained catheter, and did not replace it; but the result of the experiment was not such as to encourage me voluntarily to repeat it. The first day, the patient passed urine in an excellent stream; but afterwards the stream became very much smaller, and there was considerable pain during micturition. It was not until a week afterwards that a No. 10 could be again introduced with facility, smaller instruments having been passed in the meantime, but not fastened in.

The questions, as to whether a catheter should be fastened in after the operation, and, if so, how long it should be retained, appear to me

to be very important, in regard both to the rate of progress and to the ultimate result of the case. I am inclined to think that the catheter should, unless contraindicated, be retained until the granulating process has been fairly established on the cut surfaces. But the only safe rule appears to me to be that in this, as in other points in practice, we must always be guided by the conditions and indications presented by the particular case with which we have to do, regardless of any hard and fast rule, however well founded, according to general or average experience, such rule may appear to be.

I may be permitted to give a few details of the two cases to which I have referred, as affording, in my experience, the best illustrations of the success and value of the operation.

The first case is that of a gentleman, thirty-eight years of age, who had suffered very severely from stricture of the urethra during the long period of nearly twenty years. He had had several attacks of retention, relieved from time to time by opium and hot baths. During the years 1867-1868, he was treated by constantly repeated applications of potassa fusa. After submitting to this treatment for two years, and, to use his own words, "enduring the most agonising pain with fortitude, he considered he had been sufficiently patient and persevering". No larger sized instrument than a No. 2 could ever be got into the bladder. He gave up his case as hopeless, and went to reside in Jersey. While there, his sufferings were somewhat diminished. He returned to London in January 1870, and again submitted himself to the potassa fusa treatment; and, although he experienced no benefit whatever and suffered excruciatingly, he continued some months under this treatment, and then gave it up in despair. From May 1870 to May 1876, he received no surgical treatment whatever, the frequent attacks of retention being relieved by opiates, warm-baths, and suppositories. He became altogether "incapacitated from attending to business, could not enter society, and indeed was unable to venture many yards from home, in consequence of the bladder being unable to retain more than an infinitesimal quantity of urine". "More than fifteen minutes' sleep at a time could not be taken; and by May 1876, his general health was completely broken down, and his condition was such that neither he nor his friends believed he could survive much longer." Under such circumstances, I saw him; and his condition was indeed deplorable. Any attempt to touch the urethra with an instrument gave rise to the most excruciating pain; and it was obvious that, even supposing a fine instrument were introduced under chloroform, it would be impossible to retain it so as to effect any good. The bladder was in most wretched condition. The only thing to be done appeared to me to afford relief by means of opening the urethra behind the stricture, according to the method of Mr. Cock. This I did with most satisfactory result. His sufferings were at an end. He slept excellently well the whole of the night after the operation. The bladder, which before more resembled a sloughy abscess-cavity than anything else, gradually regained a healthy condition, and he steadily progressed, gaining health and strength until, free from all pain, he was able to get about, comparatively strong and well, with ease and comfort. He passed his urine freely through the perineal opening either with or without the aid of a catheter. I have mentioned these details to show the severity of the case with which I had to do. For some months, he was so well satisfied with his condition, that he declined to have any attempt made to restore the natural passage. In January of the present year, he wished, however, to have an attempt made; and, accordingly, chloroform having been administered, I performed internal urethrotomy in the manner I have described. There was some considerable difficulty in getting the guide into the bladder; but the long rest the urethra had enjoyed had permitted, at any rate, some of the inflammatory swelling to subside, and I was able to succeed. By alternately projecting the blades of the instrument and pushing on the bulb, I at last succeeded in tunnelling through all the strictured part of the urethra. The cutting must have extended through a length of at least two inches and a half. A No. 10 catheter was at once passed and fastened in. There was very little bleeding. From the day of the operation, the patient never suffered any pain worth speaking of, nor had he any bad symptom of any kind. The passage was perseveringly kept open by catheters, retained at first, and afterwards introduced whenever he wanted to pass urine, for some time; and the perineal opening was allowed to close. Now, seven months after the operation, he passes urine in a good full stream, and a No. 10 catheter slips along the passage without hitch or hindrance. The urine is clear, and he has returned to active business occupation. I know no other method by which a like result could have been expected to have been attained.

The other case is that of a patient, thirty-six years of age, who had been the subject of stricture, gradually increasing in severity during ten or twelve years. He had led a very hard life in India and South America, constantly in the saddle, exposed to all sorts of hardships, and

never able to get proper surgical treatment. When he came under my care, in March last, his perinaeum and scrotum were riddled with sinuses, through which the urine escaped, only a few drops coming from the orifice of the urethra. He was emaciated and broken down in health, and was evidently suffering most severely. After several attempts, I passed a No. 1 elastic catheter into the bladder, and, two days afterwards, performed internal urethrotomy. In this case, I had to cut through three distinct strictured portions instead of one continuous one. A No. 10 catheter was passed and fastened in. The sinuses were laid open to such extent and in such manner as seemed desirable. No bad symptom followed; but the greatest relief was experienced. In three weeks, the patient was up and about. The sinuses had apparently almost filled up. He was not allowed, however, to pass his urine without the aid of the catheter for another fortnight or three weeks, at the end of which time the old sinuses appeared fairly closed up. The improvement in general health and condition was rapid and marked. Three months after the operation, he declared himself better and stronger than he had been for years, and altogether free from pain and trouble about his urinary organs. He continued, however, to use the catheter at least once daily.

How far the good results obtained in these, and the other cases to which I have more briefly alluded, will prove permanent, remains to be seen. But, at any rate, a large measure of immediate relief has been afforded. And I cannot help believing that the new cicatricial tissue of an incised surface may prove less likely to contract speedily than the tissues around a stricture after ordinary methods of dilatation, and to become the seat of fresh inflammatory swelling and thickening.

In conclusion, I would venture to say that, although I have spoken so far in favour of the operation of internal urethrotomy, and so hopefully as to the results to be expected from it, I should be very sorry to leave the impression that I would advocate or practise this operation indiscriminately in all cases of stricture. For ordinary cases, I believe the ordinary method safest and best. Internal urethrotomy must be regarded as an exceptional operation, to be practised in exceptional cases. But, as such, I believe it well worthy of adoption—at any rate, of more extensive trial than it has yet had in this country.

## ON STRICTURE OF THE URETHRA; WITH SPECIAL REFERENCE TO URETHROTOMY.\*

By EDWARD ATKINSON, M.R.C.S., F.L.S.,

Surgeon to the General Infirmary, Leeds; and Lecturer on Surgery at the Leeds School of Medicine

THE selection, by the officers of the Section, of Stricture of the Urethra, with special reference to Urethrotomy, as one of the subjects on which they invited discussion at the present meeting, must be my apology for offering the following remarks, rather than because I have much that is new either to suggest or to relate.

Perhaps their choice may owe something to the remark of my colleague Mr. Wheelhouse, in his communication to the JOURNAL last July, upon his method of performing perineal section: that, although the operation, as performed at Leeds, had been before the profession for some years, having been published by him in 1869-70, it had received but little notice either in the journals or in recent surgical works. Be that as it may, Mr. Wheelhouse's letter was followed in three months by the appearance of Mr. Teevan's most interesting and ingenious paper on an Improved Method of Performing the *Boutonnière* Operation, in which he truly says: "In Leeds the operation is performed systematically, frequently; and I should say that, in that town, it is done more often in one year than in all the hospitals in London put together during the same period."

In support of this statement, I may say that I have performed it myself nine times in the last three years in hospital and once in private, and that each of my colleagues has done it many times within the same period. I can also assert that, of my own ten cases, eight were successful, and of most of them that they were seen several months after their discharge from hospital, when the results were found to be quite satisfactory as regards the cure of the stricture. In no case had perineal fistula resulted, and in one only had there been any untoward effect of any other description. To this case I will refer more particularly afterwards.

The two instances in which I was unsuccessful were both desperate cases. In one, extensive extravasation of urine had occurred before admission; in the other, there were large abscesses both in the scrotum and perineum, with several fistulous openings from old abscesses, and

the patient was in a very low condition generally. Both these cases died within three to six days after operation.

The total number of operations for perineal section, done in hospital during the last three years, is thirty-nine, of which seven died; this gives a mortality of nearly 18 per cent.

According to surgical authorities, both English and French, various modes of procedure for the relief of stricture by urethrotomy are recommended; some of which are deemed to be preferable in one class of cases and some in another. Distinctions are drawn between the circumstances which render this or that operation the most applicable to a given case. Thus, in old cartilaginous strictures of the membranous portion of the urethra, complicated or uncomplicated by fistulae in the perinaeum, one or another modification of the *boutonnière* operation is preferred. In cases of retention, where all attempts to pass an instrument through the stricture fail, and the urethra is distended behind the constriction, Mr. Furneaux Jordan counsels the opening of the distended urethra and division of the stricture from behind forwards; while in very tight strictures, where extreme sensibility of the passage resists treatment by dilatation beyond a certain limit, or where such treatment, as soon as discontinued, is followed by a return to the *status quo ante*—and especially when the stricture of this character exists in any part of the straight portion of the canal—internal urethrotomy by Civiale's method, or some modification of it, is often advised.

It is no doubt true of these operations, as it is of many other surgical procedures, that one method proves more frequently successful in the hands of one surgeon, while another method succeeds best in the hands of his friend. This is intelligible enough; for he who has familiarised himself with the steps and the minute details of a given operation, by the habitual adoption of it in a long series of cases (in which numerous varieties of conditions are sure to occur), is more likely to be able to accommodate it to the special requirements of an exceptional case; whereas his occasional adoption of a different method, with the minutiae of which he was not so familiar, might not improbably result in disappointment.

At Leeds, it has now for some years been customary to pursue that mode of perineal section—or "*boutonnière*," as Mr. Teevan prefers to call it—(though why we should go to the French for a name when English serves our purpose I do not exactly understand) which has been fully described by Mr. Wheelhouse; and this, not only in the class of cases referred to above, but in almost every instance where it is considered necessary for the cure of a stricture, whether literally impermeable or not, to incise it, so as to pass a full-sized catheter into the bladder.

The main features of the operation (though they are before the profession) may be briefly epitomised here.

1. The introduction of Wheelhouse's straight button-ended staff, grooved to within half an inch of its extremity, down to the strictured point, with the groove looking forwards.

2. The opening of the urethra *in the groove and not upon the point* of the staff, so as to secure at least a quarter of an inch of healthy urethra in front of the stricture.

3. The seizing of the cut edges of the wound in the urethra by two pairs of straight-bladed nibbed forceps, while the staff is turned round and withdrawn sufficiently to hook up the upper angle of the opened urethra. A lozenge-shaped window is thus obtained, through which the stricture can be seen, and often the orifice in it can be detected.

4. The introduction of a finely probe-pointed director into the stricture, and through it on towards the bladder. This, of course, is the *crux* of the operation. It is readily to be conceived that, in cases complicated by false passages, the danger of proceeding to cut on the director, upon the supposition of its having entered the bladder, when it has not, should haunt the mind of the operator; but, as a matter of fact, I think I am justified in quoting Mr. Wheelhouse's expression, that its entrance is "clearly demonstrated by the freedom of its movements." Though difficult cases sometimes occur, I have never seen one in which the director has failed to guide safely.

5. The groove of the director having been turned *downwards*, the stricture is divided on its under surface by the scalpel, and a straight probe-pointed bistoury is afterwards carried along the groove, beyond the external wound, to insure complete division of all obstruction; and then,

Lastly, a most important and essential step, in order to insure the safe conduct of the catheter into the bladder: Teale's probe-gorget is guided along the grooved director into the bladder, dilating the stricture, proving by the gush of urine which flows along it that the viscus is reached, and forming a metallic floor over which the silver catheter cannot fail to pass safely to its destination.

Of the eight cases successfully operated on by myself, three were old cartilaginous strictures, which would admit of no instrument being passed through the meatus. Two belonged to the category of tight

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

strictures in highly irritable urethrae, which admitted the passage of a No. 4 and No. 6 catheter respectively, but resented further dilatation, which always set up constitutional disturbance. One case was admitted with complete retention; and hot bath, chloroform, opiate enemata, and the evacuation of the bladder by the aspirator, having failed to obtain the introduction of any instrument through the stricture, urethrotomy was resorted to. The last case in which I operated came under none of these heads. He was a man aged 46, who had suffered from spasmodic stricture for five or six years. He was a highly nervous subject and a thorough hypochondriac. Attention to his diet and general health, and the occasional passing of a catheter after a few days' rest in bed, gave only temporary relief. If I attempted to introduce an instrument when going round the wards with my class, I never succeeded; but on returning to him alone half an hour afterwards, I could pass No. 12. Thinking that, by opening the urethra in the perineum and allowing the urine to drain away for a week or two, I should give the irritable urethra a complete rest, and so permanently relieve the spasm, I consulted my colleagues on the case; and, as they all fully concurred in my hopes of the good to be anticipated from such a course, I performed perineal section, freely dividing the membranous portion of the canal throughout its extent, and, having introduced a full sized catheter, withdrew it again, and did not reintroduce it for ten days. This case is still under treatment, but hitherto there seems to be every prospect of a favourable result. Whenever the catheter has been left in in this case, even for four or five hours, a severe urethral rigor, with sudden rise of temperature, has taken place, and that since, as well as before, the operation, sufficiently showing the sensitive condition of the part; and showing also, I think, not only the insufficiency, but the inappropriateness, of treatment in this instance by dilatation alone.

I have now only to refer to the case in which an untoward effect followed the operation, and which was not discovered until six months afterwards.

The patient was a young tradesman, aged 25, who consulted me for a tight and somewhat oblique stricture seated at the junction between the spongy and membranous portions of the canal. No metal instrument would pass, but after many trials I passed a soft *cathétère à boule*, first a No. 3, and at subsequent sittings Nos. 4 and 5. Beyond this point I made no advance; and in addition to the unyielding character of the stricture and its obliquity, the urethra was so exquisitely sensitive, that every time the instrument was used, though with the most gentle manipulation and without ever causing bleeding, the patient was in pain for twenty-four hours or more after it. I therefore resolved on dividing the stricture, and, accordingly, performed perineal section, in the manner above detailed, in September 1875. The bulb was notched, and the anterior half of the membranous portion was divided in the middle line. The stricture was cleanly divided, and the probe-*gorget* having been used to dilate the posterior portion, a full-sized silver catheter was carried along it into the bladder and retained for thirty hours only. After this, it was introduced every second day for a fortnight, then twice a week for a fortnight more, when he went into the country; but visited me once in a week or ten days to have the instrument passed. The perineal wound closed at the end of three weeks after operation, and he never had a bad symptom nor failed to pass his urine in a good stream. Six months afterwards, he married; and in April 1876, he came to me complaining that he had no satisfaction *in coitu*. The act was completed, but there was no ejaculatory power. The seminal discharge was emitted (or, as he expressed it, "oozed out"), without any sensation of propulsion. I imagined that this was due to recontraction of the canal, but found no difficulty in passing a bougie, and he afterwards passed urine, without assistance, in a good stream. I encouraged him to hope that he would regain the power in time, and recommended him to abstain from sexual intercourse for a while; but several months later, he returned with the same story, and more downcast than before, because there was no promise of his marriage becoming fruitful. Now, what had happened? Was it the division of the fibres of the accelerator muscle? This would have been the explanation which would probably occur to one at first. But is this muscle the real agent of ejaculation? According to Professor Küss of Strasburg it is not; or, at any rate, only in a secondary degree. That physiologist says: "At the moment that the sperm is poured into the prostatic portion, this portion of the canal is isolated from the bladder, on account of the turgescence of the *verumontanum*, which is, during erection, in contact with the anterior wall (as shown by Kobelt); and we all know that micturition is impossible during the state of erection. On the other hand, the efferent ducts of the vesiculæ seminales, incorrectly called "ejaculatory ducts" open in front of and at each side of the *verumontanum*; so that the sperm readily passes into the prostatic urethra, which it fills up, but it can go no farther, because at this moment the urethral sphincter (called Wilson's muscle)

contracts and obliterates the membranous portion. The fluid, therefore, accumulates in the straight part of the canal between these two points under high pressure. But the sphincter muscle cannot long maintain its contraction; it relaxes, and immediately the seminal fluid is ejaculated with force due to the sudden relief of the pressure, while the rhythmical character of the emission is due to alternate contraction and relaxation of Wilson's muscle; though doubtless, also, the contact of the seminal fluid with the mucous surface influences the intermittent and tetanic contraction of the urethral sphincter." (Küss.)

It appears to me, therefore, that in the case related above, the loss of ejaculatory power is more probably the result of injury to Wilson's muscle, or the nerves supplying it, either by division or distension, than to injury of the bulb or the bulbo-cavernous muscle, generally called the ejaculator seminis. Whichever be the true explanation, it appears singular that this result should not be more frequently heard of after perineal section.

## ON INTERNAL URETHROTOMY.\*

By W. F. TEEVAN, B.A., F.R.C.S.,

Surgeon to the West London Hospital; Surgeon to St. Peter's Hospital; etc.

WITHIN the past few years, the operation of internal urethrotomy has occupied much attention in this country; the principles of the procedure have been more clearly established and better carried out, great improvements have been effected in the instruments used, and I think it may be safely predicted that internal urethrotomy will, in the future, attain that position to which it is justly entitled.

I would firstly remark that I consider most urethral strictures are best treated by gradual dilatation, carried out by means of soft instruments; that an operation is but seldom called for, and ought, as a rule, to be only resorted to after milder measures have failed. I would also observe that, pathologically, there is no evidence to prove that a stricture can be cured; but practically all strictures are curable, provided an instrument is occasionally passed at regular intervals for life.

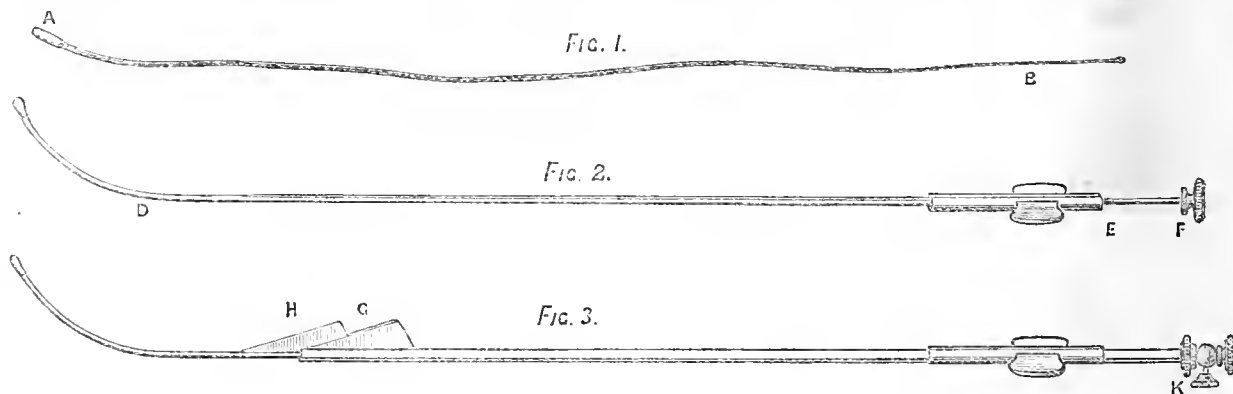

Now, if an operation be indicated, what are the requirements it must fulfil? what, in fact, is demanded of it to prove successful? I do not think the answer can be found in any English work; we must ask French or American surgeons. The former would reply that the insertion of the "*pièce d'allongement*" is required; whilst the latter would say that a "cicatrical splice" is wanted. The above expressions convey, in a very clear and concise manner, what is indicated. We have to enlarge the contracted urethra by letting into it a splice of new tissue, which is of a necessity cicatrical. We know that cicatrices are endowed with varying powers of contraction; those, for instance, which result from the clean cut of a surgeon's knife shrink but little, whereas those following lacerations contract greatly. Hence, therefore, a cicatrix made by a clean incision possesses the minimum amount of contraction, whilst that following a laceration has the maximum degree; and, inasmuch as we want a cicatrix which will contract as little as possible, we must choose a cutting operation, and not a tearing one, like the so-called "immediate dilatation".

Let us not forget these two following important surgical facts, which we constantly see, and which vividly show the relative results of cutting and laceration. When a surgeon incises the healthy urethra of a man, in the operation of lithotomy, no stricture follows when the wound is healed; but if the same man had been kicked in the perineum and his urethra torn, a stricture of the worst description would have ensued. Hence our choice is limited to cutting operations. Now, there are three forms of urethrotomy—external, subcutaneous, and internal. The external I regard as a severe procedure, which ought to be very rarely required; the subcutaneous is only adapted for cases where there is but a single stricture; whilst internal division can deal with any number of strictures; and, as it is a procedure which is attended with but little risk to life, it must be regarded as our stock operation for stricture. In what cases would I operate? If the stricture be non dilatable, or, if dilatable, it contract again as fast as it is stretched; or if there were numerous fistulae combined with a tough stricture; or if the process of gradual dilatation were attended with great pain or constitutional disturbance; or, lastly, if continuous dilatation had failed. It may also be premised that penile strictures and those of traumatic origin are not usually amenable to dilatation, and require to be cut. Having determined on internal urethrotomy, shall we divide the stricture from before backwards, or from behind forward? The answer to this question has divided surgeons into opposite camps, and acrimonious discussions have taken place. As both parties have obtained good results, they have

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

each attributed them to the particular method they have employed. I would venture to say that, in the hands of a skilful operator, equally good results will follow either method, but that the division from behind forwards requires a great deal more skill and care than the other, in order to determine the length of the incision, for it is not always so easy to judge where it shall end. The cutting operations may be of two kinds. Firstly, scarification. In this operation, a number of notches or small cuts are made into the stricture, but not through it, for they are not extensive enough for that. The instrument which makes the cuts is called a scarificator, and usually has two, three, or even four small blades. Secondly, internal urethrotomy, in which the stricture is completely divided at one cut by an instrument named an urethrotome, which generally has but one blade. There is a very great difference in the results of the two operations. The scarificator merely notches the stricture sufficiently to allow itself to pass through, whereas the blade of the urethrotome cuts the stricture in two, and permits of the passage of a vastly larger instrument than itself, for the simple reason that, the stricture having been completely divided, there is no longer any resistance. At one time, scarification was much employed in France; but it has, I think, been almost completely abandoned, as the results obtained by it were of a very fleeting character. It has been almost unanimously and emphatically laid down by French and American surgeons that, to obtain a good result, a stricture must either be torn through or cut through; and, as the former operation does not

of the stricture, and so prevented their division. I have removed the button on the blade, and protected the urethra from injury by encasing the knife, ~~in~~ (see fig. 3) in a double sheath, G. The peculiarity of my double sheath is, that it runs outside the staff in telescopic fashion, and not inside it, as in the urethrotomes of Sédillot and Gouley. By this modification, the calibre of the staff is not increased in bulk, whereas it is greatly strengthened by the stem attached to the sheath embracing it. The sheath also represents the surgeon's finger in the urethra; for it feels for the obstruction, tells him where it begins; and, when he thinks he has divided the stricture, it assures him of the fact or otherwise. Lastly, it makes the parts tense for us when we stretch the penis forcibly upwards towards the handle of the urethrotome. I have had the end of the staff of the urethrotome tunnelled like Dr. Gouley's, so that the instrument can either be slipped over a fine filiform bougie introduced into the bladder, or it can be screwed on to the "bougie conductrice", ~~as in fig. 1~~, and made to follow it into the bladder. The groove in my staff stops at D (see fig. 2), two inches from the end; so that, when the urethrotome is in the bladder, the curved non-grooved extremity is in the prostate and bladder. Inasmuch as there is never any stricture in the prostate, there is no object in carrying the groove to the end of the staff, as it is in the urethrotomes of Sédillot, Gouley, and Maisonneuve. The conducting bougie ~~as in fig. 1~~ is of great value; for in some cases it is impossible to introduce the urethrotome, not because the stricture is so tight, but because the passage is so tor-

fulfil the requirements I have alluded to, it only remains for us to cut completely through the contraction with the urethrotome.

An enormous number of urethrotomes have been invented, and many of them have, I think, earned the late Professor Syme's condemnation, that they were "terrible engines of war". Until a few years ago, Civiale's urethrotome was, perhaps, more used than any other for dividing from behind forwards, and Maisonneuve's for cutting from before backwards; the latter instrument has been considerably improved. A good urethrotome ought to fulfil the following indications. 1. It should, when introduced, declare with certainty whether it be in the bladder or not. No urethrotome ought to be used which does not do this, for much discredit has been unjustly brought on internal urethrotomy by surgeons employing instruments which did not prove where they had gone to. Hence, false passages, and even the rectum, have been divided instead of the stricture. 2. The knife should not wound the healthy urethra. 3. The staff of the urethrotome should be very slender, so that it can be passed through very tight, narrow, non-dilatable strictures. 4. The instrument should not only tell where the incision is to begin, but where it is to end.

Now I believe that the urethrotome, as modified and improved by Sédillot, Gouley, and myself, fulfils all the above requirements. In Maisonneuve's instrument, the groove in the staff extended through its entire length, so that the knife went into the bladder, which was unnecessary; and, as the slit was usually blocked up by blood or mucus, and hence the withdrawal of the urine, which formed no part of the operation, could not be effected. The groove in my staff is filled with a closely fitting stylet (see fig. 2), so that, when the wire is taken out, urine will flow if the instrument be really in the bladder. Maisonneuve thought he had protected the healthy urethra from possible injury when he put a metal knob or button on the apex of his triangular blade. *Post mortem* examinations made in Paris and New York demonstrated that with his knife the healthy urethra might be cut in numerous places undesignedly. In one instance, the mucous membrane of the canal was cut in its entire longitudinal axis. Then, again, this knob on the blade pushed away some of the outlying fibres

tuous. If, however, the bougie be first passed, and the staff of the urethrotome be screwed on to it, it will follow the former into the bladder. This procedure must be conducted very slowly, otherwise the bougie may be doubled up if the urethrotome be pushed too quickly after it. When the instrument is apparently in the bladder, I withdraw the stylet E F (see fig. 2) to verify its position. If urine flow, I operate; if it do not, I withdraw the urethrotome and try again another day. Supposing, however, that the urine escapes, I stand on the right of the patient, and take the knife enclosed in its double sheath, and, protruding the former a little, I insert it into the groove of the staff, and immediately slip the double sheath over and outside the staff. I then withdraw the knife within the sheath, and, clutching hold of the penis just behind the gland, I draw it forcibly towards the handle of the urethrotome, which is held by an assistant standing opposite me; and with the right hand push the stem of the sheathed knife slowly down the urethra till it arrives at the obstruction, against which I keep it steadily pressed. By these two manoeuvres, I have ensured that the stricture is made perfectly tense, so that it can be cleanly and completely divided. I now protrude the knife for half an inch, knowing that that is the minimum cut required to divide even a ring-stricture not thicker than a thread. The knife is then withdrawn into its sheath, which is pushed forwards to see if the stricture be completely divided or not. If it be not, the process is repeated, each cut being half-an-inch long, till everything is cut. I generally divide the strictured urethra in the roof, as I think that is the best situation, for the bulb is thereby avoided. If the surgeon prefer, however, to cut the floor of the canal, all he has to do, when he has passed the staff of the urethrotome, is to reverse the instrument, so that its point is turned behind the prostate, as in lithotomy. The urethrotome can be made with a lateral or inferior blade, if desired. As soon as I have ascertained that the canal is perfectly free from one end to the other, I withdraw the instrument and introduce a No. 25 silver catheter, for the purpose of demonstrating that the urethra has been restored to its normal calibre and to completely empty the patient's bladder. By ensuring that the bladder is empty, the patient can go for some four or six

hours without wanting to make water, by which time the wound will be covered with a firm clot, and the pain in micturition be considerably diminished. I do not leave any catheter in the bladder after the operation, and I allow the patient to pass his urine naturally. I believe I was the first surgeon in this country to dispense with the use of the catheter after the operation. If there be one practice more persistently insisted on than another in English surgical works, it is that of the necessity of the use of the catheter after urethrotomy, the instrument to be either left in the bladder or else employed to draw off the patient's urine; and the writers point out the disastrous consequences which will take place, in the shape of abscess, fistula, or infiltration of urine, if the practice be not observed. To Dr. Gouley of New York belongs the credit of having shown the utter groundlessness of the surgeon's fears.

After the operation, I am in no hurry to commence the passing of instruments, usually waiting till the fourth day, and not introducing them oftener than twice a week. At the end of ten days, I begin to teach the patient how to pass a catheter for himself, and order him to do so every Saturday night till further orders. By passing a large No. 25 bougie or catheter several times after the operation, the insertion of a good "cicatrical splice" is guaranteed.

Now as to results. I have operated in all on thirty-three cases, all of them of the worst description, and for that reason relegated to the operation, without a single death. In one instance, the urethra was so indurated in its entire length that I left in a catheter after the operation, to set up urethritis, and so lessen the thickening. The inflammation was, however, more than I desired; and abscess, followed by fistula, ensued. The case ultimately got quite well. In one case only had I troublesome bleeding. It proceeded from the meatus, which I had divided, and was a hint to me for the future not to cut the meatus at the same time as the stricture, but several days before. As a rule, not more than about a dessertspoonful of blood escapes either at or after the operation. Secondary hæmorrhage I have never seen. Rigors occurred in about two-thirds of my cases. I look upon them as entirely nervous and of no importance. It is stated in books that rigors are due to the passage of the urine over the wound. This, however, cannot be the correct explanation; for, unless pyæmic, they are never seen after lithotomy or external urethrotomy. I look upon rigors after internal urethrotomy as caused by the sudden stretching of the nerves in the wound through the distension of the canal by the urine. In three of my earlier cases, I had to repeat the operation, as my incisions had not been sufficiently free. I am sure that every one who performs the operation will be pleased with the soft supple cicatrix which follows it, so different from the rough, tough, irregular cicatrix which forms the so-called "immediate treatment", which is neither more nor less than absolute laceration, not always of the tough stricture, but sometimes of the unoffending healthy urethra, where, as elsewhere, "the weaker goes to the wall".

Now for statistics. I think they will be found to be eminently satisfactory, and will carry conviction. They are the largest, I believe, which have ever been placed before the profession, and show what internal urethrotomy can accomplish. No other operation for stricture with which I am acquainted can produce such favourable results. I consider that no operation can be performed on the urethra without a certain amount of risk; but how slight that risk is you will immediately see. I find by examination that the operation has been performed by six surgeons in London, Paris, Mobile, and New York, one thousand and ninety-five times, with but ten deaths; and there would probably have been two deaths less had it not been for the crowded state of the wards in the Necker Hospital during the Commune.

In conclusion, gentlemen, let me say that the deductions drawn from the experience of a solitary surgeon may be misleading, but that the conclusions which must be arrived at from the overwhelming mass of figures which I have placed before you loudly proclaim that the operation of internal urethrotomy claims your consideration and demands your support.

#### NEW MODE OF TREATING VARICOCELE.

I find the following simple procedure an efficient method of treating varicocele. Pass a long and strong hare-lip pin between the veins and the scrotal walls, bringing the point of the pin close beneath, but not through, the scrotum; then make the point retrace its course, but passing now behind the veins, until it emerges near the puncture through which it entered. In a word, by employing that form of acupressure known in the Aberdeen School as the method of retroclusion, a varicocele may be effectually compressed and the veins obliterated.

S. MESSENGER BRADLEY, Manchester.

#### HISTORY OF OVARIOTOMY IN ITALY.

By T. SPENCER WELLS, F.R.C.S.,  
Surgeon to the Queen's Household, &c.

I HAVE just received from Dr. Peruzzi of Lugo a pamphlet upon my practice of ovariectomy. This pamphlet, which is a reprint of articles in the ninth volume of the *Rivista di Medicina*, consists in great part of a translation of one of my lectures, published in the *BRITISH MEDICAL JOURNAL* of December 15th, 1877. It also contains so very cordial a recognition of the effects of my work upon Italian surgery, that I should have received it with silent gratification, if it had not also contained a correction of an historical error into which I had fallen, but which I now hasten to acknowledge and correct.

In my work on *Diseases of the Ovaries*, there is a chapter on the Rise and Progress of Ovariectomy. At page 314, the following sentence may be found: "In Italy, the first successful ovariectomy was performed by Professor Landi of Pisa, in September 1868; the second by Professor Peruzzi of Lugo, in 1869; the third by Dr. Marzolo of Padua, in July 1871." On page 313, I had stated that Professor Vanzetti, the distinguished Italian surgeon, had performed the first ovariectomy in Russia in 1846. My work was published in 1872; and Dr. Peruzzi is not unnaturally surprised that I did not allude to a case by Emiliani of Faenza, in 1815, which had been published in 1843 in the *Bullettino delle Scienze Mediche di Bologna*, and had been again brought to light by Dr. Peruzzi himself, in the form of a letter to M. Boinet, entitled "*Aperçu Historique sur l'Origine et les Progrès de l'Ovariectomie en Italie*".

As this letter appeared in *L'Appreciation di Forlì* in 1869, I should certainly have noticed it in 1872, if I had seen it. I now see it for the first time, in pamphlet form, reprinted from *L'Appreciation*.

The author shows that, so long ago as 1752, Dr. Tazzioni Tozzetti, in a published *Selection of Medical Observations*, had not (as supposed by Boinet) proposed to extirpate a diseased ovary, but only discussed the question of tapping and palliative treatment. So Morgagni, in 1761, admitted that ovariectomy might be considered in cases where the cyst was not adherent and the pedicle single and slender. Peruzzi goes on to quote from Monteggia in 1814, and Sacchi in 1832, sentences to prove that these surgeons were theoretically in favour of ovariectomy. These will not much interest your readers; but the account of the case of Emiliani, in 1815, is very remarkable.

Dr. Gaetano Emiliani of Faenza was a provincial surgeon. A married woman, twenty-six years of age, mother of three children, while nursing her third child, lifted a heavy pan of water, resting the edge of the pan against the lower part of the abdomen. There was no immediate suffering, but the next night she was awakened by acute pain in the left iliac region, which continued during the next day. Dr. Brunetti was called, and "discovered at the seat of pain a tumour almost isolated in the cavity, without any alteration externally, very painful to the touch". Four months passed without much relief, and the patient suspected pregnancy. In two months, with a great loss of blood, she passed a very large mole ("*una assai voluminosa mole*"); uterine discharge continuing for twenty-five days. Dr. Emiliani was called in, and found his patient feverish, with evening exacerbations; the tumour, a hard circumscribed spheroid, indolent to the touch, but the seat of occasional spasmodic pain. The diagnosis was "scirrhus condition of the ovary and tendency to carcinoma", and the only hope, extirpation. The proposal was approved by Brunetti, who, with a phlebotomist, assisted at the operation, which I describe in the words of the son of the operator, who first published the account of the case.

"My father divided the common integument along the linea alba for about two inches and a half, divided the subjacent muscles and the peritoneum very carefully, and exposed the left ovary, which was recognised by its position, form, connections, although enlarged beyond all ordinary degrees, scirrhus, superiorly covered by small vesicles, from which a fetid ichor ran, and adhering by its whole inferior part to the colon; around, some varicose vessels were observed. The ordinary connections and the unusual adhesions were promptly separated, and the arterial twigs were tied one after another as they were divided. The blood lost was calculated at less than half a pound. The lips of the wound were united by one suture."

The after-treatment appears surprising in these days—rigid diet, bleeding repeated on the following day, tartar emetic, and lemonade. But recovery was complete; menstruation reappeared; and a year after the operation twins were born, which both died after a few hours. Five other children were born after these, two of whom, with their mother, the patient, were alive and well when the report of this case

was published by the son in 1843. Dr. Brunetti and the phlebotomist were also living.

"The ovary, after having been preserved twenty-eight years in alcohol, is pyriform, is nine *centimètres* long and five in its greatest breadth (three inches and a half by two inches). The peculiar structure is searched for in vain, being entirely degenerated by scirrhus. The specimen has been taken from my private museum, and is now deposited in that of the illustrious Medico-Chirurgical Society of Bologna."

There are several interesting points in this narrative. The ligatures appear to have been left in the abdominal cavity; and it is certainly desirable that the specimen should be carefully examined. If it be really an ovary, it will certainly appear that the first case of ovariotomy in Enrope was that by Emiliani of Faenza in 1815. I have written to Dr. Peruzzi, suggesting that the specimen should be examined by some competent morbid anatomist.

## THE CONNECTION BETWEEN STOMACHIC AND LABYRINTHINE VERTIGO.\*

By EDWARD WOAKES, M.D.Lond.,  
Surgeon to the Throat Hospital.

A GREAT deal of attention has recently been devoted to what is commonly called Menière's disease, but, which, from the anatomical organ to which the symptoms are mainly referred, is also known as labyrinthine vertigo. The elaborate treatment of Dr. Gowers, Dr. Hughlings Jackson, and Dr. Ferrier compasses the present knowledge of the subject, so far as it relates to that form of vertigo resulting from the progressive invasion of the labyrinth from lesions of the middle ear.

But there is another class of vertiginous patients in whom the auditory apparatus is, up to the time of the attack, perfectly healthy, and may remain so after it has passed off, whose symptoms are, nevertheless, due to a more or less temporary lesion of the labyrinth, to which organ, in fact, the general consensus of opinion refers every such disturbance of equilibration as expresses itself in giddiness. It is to this class of cases I wish to invite your attention this evening, and, as in their investigation we shall get some insight into stomachic vertigo, the area of interest of the subject will be proportionately widened.

The form of vertigo to which I allude is that in which the patient, without being aware that he is otherwise than quite well, is suddenly attacked with giddiness and falls prostrate. This may never in that patient's experience be repeated, or the attack may recur after a shorter or longer period. The cases in question differentiate themselves from those treated of by the authors referred to in the fact, already stated, that the auditory apparatus is previously quite healthy, though they possess this feature in common with them: that there is no loss of consciousness. After the attack, the patient finds himself in one of the following conditions: his hearing may be normal, as heretofore; or he may be quite deaf on the side to which he fell; or there may remain some impairment of hearing only, with probably confused noises in the head.

As regards concomitant symptoms, nausea and a splitting headache may remain. There is also a painful sense of fear, a horror lest the attack should be repeated, and a dread of becoming epileptic; to which apprehension the members of our profession who suffer from the attacks are specially prone.

The following example, the subject of which was a medical man personally known to me, illustrates some of their features. When about thirty years of age, and being fully engaged in a very arduous country practice, he was one evening summoned to a patient, being already fatigued with the usual day's work. On reaching the house, he became giddy, and, as the door was opened, fell into the hall, a proceeding which, though perfectly conscious, he was quite unable to avoid. It is needless to say he was very much frightened by the attack, but was not otherwise affected by it. In the course of the following year, a second seizure occurred exactly corresponding in character to the former; but, for more than twenty years subsequently, there was no repetition of the attack, although he was for a lengthened period the subject of intense headaches, with tinnitus, for which he submitted to the ordinary method of depletion then in vogue.

The time at which these events happened was over thirty years ago. Menière's disease was, of course, unheard of; and Flourens had not yet experimented on the semicircular canals. It was not, therefore, extraordinary that this patient should be haunted with the dread of becoming epileptic.

Adhering to the principle laid down in a former paper, we shall seek the clue to the symptoms in the source and vaso-motor relations

of the blood-vessels supplied to the region manifesting them: a proceeding which will show that this particular region, the labyrinth, possesses some very remote, and possibly unlooked for, alliances. At this point, it will be necessary to repeat what I have elsewhere had occasion to insist upon; viz., that the receptive part of the auditory apparatus receives its vascular supply from a totally distinct source—the vertebral artery—to that which is furnished to the conductive portion of the ear. This in itself is a suggestive fact, as the internal carotid, in its bony canal, is placed so close to the internal ear that one might naturally look to it as the source whence its vessels would be derived. As a matter of fact, however, neither the external nor internal carotid is in any way concerned with the circulation of the labyrinth. It is the vertebral artery and its relations we have to consider. The origin of this vessel, from the subclavian deep down in the neck, and its prolonged course upwards, guarded by the bony sheath formed by the vertebral foramina, acquire an increased importance when its relations to certain nerves are considered. In the first place, this position brings it into very close proximity with the inferior cervical ganglion, from which it derives a rich plexus of nerves, communicating, in their upward course, with the several cords which form the brachial plexus. It is important here to note that this lower cervical ganglion furnishes also the principal inhibitory nerve of the heart; viz., the inferior cardiac nerve. The experiments of Burdon Sanderson and others show that this nerve is capable of slowing the heart's action even to the extent of stopping it. We wish to point out its close relationship with the nerve which regulates the supply of blood to the labyrinth, both passing through the same sympathetic ganglion. Nor can it be without design that such an arrangement exists. Glancing for a moment at one aspect only of the functions of the semicircular canals, that, viz., by which, under circumstances of altered tension of their endolymph, they are capable of causing the individual to lose his equilibrium and fall to the ground, we get some insight into the object gained by associating the nerve which regulates this tension with that which tends to check the heart's action. The connection is such that an impression influencing the heart will affect the labyrinth. Thus a strong mental emotion arising centrally and propagated to the heart through its inhibitory nerve, which tends to stop its action, will also be deflected in the ganglion to the nerve regulating the blood-supply of the labyrinth, and, by suddenly changing the tension in this organ, will cause the subject to fall to the ground, so removing the mechanical impediment to the circulation which the upright posture implies. In this way, time is allowed for the excited influence of the heart to subside while the subject of it is placed perforce in the recumbent attitude.

Referring now to the communication between this ganglion and the brachial nerves besides those already mentioned, there are others proceeding directly from the ganglion to the brachial plexus. It is this arrangement doubtless which explains an occurrence noticed in gunshot-wounds of the plexus. It was first pointed out by Drs. Moorhouse, Mitchell, and Keen, in a treatise on gunshot-wounds of nerves published after the late American war. These observers record most succinctly that the subject of such a wound, whether received in the arm, axilla, or neck, immediately falls to the ground, without losing consciousness. This circumstance is quite unique; it has not been observed in connection with wounds of any other correspondingly non-vital part of the body. A certain amount of collapse attends these cases, from which it may be legitimately inferred that the shock is conveyed, not only in the direction of the labyrinth, but also through its inhibitory nerve to the heart.

Anyone who is conscious of the possession of what is popularly called the "funny bone" may, if he choose, verify these statements, at least to a certain extent, by giving it a blow considerably in excess of that which is sufficient to induce the well known tingling sensation in the fingers. It once happened to the writer to witness such an experiment in the instance of a lad who was struck on this spot by a hard tennis-ball thrown with considerable violence. Immediately he became giddy and confused in his head, and would have fallen but for the support of some railings, and altogether the extreme distress which he manifested appeared out of all proportion to the slowness of the cause. At the time of the occurrence, the symptoms were quite inexplicable by any known relations of the injured part. The observation of the American surgeons just quoted, as well as the anatomical continuity established through the inferior cervical ganglion between the brachial nerves and the labyrinthine circulation, afford, we venture to submit, a ready explanation of the phenomena to anyone who candidly examines them.

It will be apparent that we are taking for granted the physiological fact, that a shock communicated to the inhibitory nerve of a vessel temporarily withdraws its function, allowing it to become greatly distended with blood; it is this sudden distension which produces the pressure on the endolymph, and the consequent subversion of the

\* Read before the Medical Society of London.

function of equilibration, which will be proportionate to the severity of the shock.

Having thus seen how labyrinthine vertigo of a very severe type may be excited through these far off alliances of the semicircular canals, we shall be in a better position to understand the corresponding relations existing between the stomach, with its adjacent viscera, and the labyrinth. Before tracing these, it will be of service to refer to Trousseau's remarks on this subject, he being probably the first writer to call marked attention to *stomach vertigo* in his chapter entitled "*Vertigo e laso stomacho*", where he discusses it with his usual candour. No one, we venture to think, can carefully study the instances he adduces of this disease without sharing the conviction that the gastric lesion was only a subsidiary factor in the production of the symptoms he refers to it. That Trousseau had himself some suspicion of this is evidenced by his own statement. Thus, after describing the case of a lady in whom distressing giddiness, brought on by the bustle of the street, the passing of a carriage in rapid motion (causes exactly calculated to interfere with the organ of equilibration, when unduly susceptible), and who became worse by depletion and abstinence from generous diet, but was cured by tonics and restoratives, he remarks:—"I have frequently asked myself whether the treatment which, in these cases, I directed against the affection of the stomach was not, unknown to me, addressed to the nervous system; and whether I had not diagnosed a gastric affection rather than the effect of treatment than from the symptoms of the disease; whether I had not been led into an error in diagnosis by obtaining success for treatment usually employed with benefit in dyspepsia." (*Lectures on Clinical Medicine*: New Sydenham Society, vol. iii, p. 544.)

In this candid commentary, my own experience of so-called stomach-vertigo would lead me entirely to concur. A fair example is afforded in the following case. A gentleman, a member of the Society of Friends, consulted me, about five years ago, for symptoms closely corresponding with those enumerated in the foregoing quotation. He was about seventy-three years of age, and, though never robust, was otherwise in good health, except that any exertion brought on giddiness, and walking in the streets was attended with a feeling that he would fall forwards. His appetite was good, although the tongue was loaded; and it was observed he had no teeth, not even artificial ones; but it was ascertained that he ate meat with a relish. In view of the edentulous state of his jaws, and with Trousseau's teaching in recent recollection, he was prohibited from taking any solid food. Small doses of bromide of potassium were given at six hours' intervals. Under this treatment, he made a rapid recovery. After an interval of nearly a year, he returned to a mixed diet, and, in a short time, his old symptoms returned, but to a less extent than formerly. The same treatment was again had recourse to with a like result, and, in the period that has since elapsed, the *role* of circumstances just detailed has been enacted on several occasions. In fact, the sensitiveness of this patient's stomach to solid food appears to be proportionate to the motility of his equilibrating nervous centre. It is a suggestive feature of this case, as also of others that have occurred to me, that the progress towards recovery was invariably expedited by the bromide. Obviously, the point at issue is how to associate stomach vertigo with the labyrinth. A very direct channel of communication is established between the pneumogastric nerve and the lower cervical ganglion by means of a fasciculus given off by the former about the point where the recurrent laryngeal leaves the trunk of the nerve. That the course of this branch is from the stomach to the ganglion will be apparent when it is remembered that vaso-motor fibres associated with cerebro-spinal nerves pursue an opposite course to the latter. When it is further remembered that nerves entering a ganglion break up and communicate with its corpuscles, by which means they contract new relationships with other nerves entering the ganglion, it will not be difficult to understand how the stomach is brought into relationship with the labyrinth. There can be no doubt, we think, that this correlation is effected in the inferior cervical ganglion through the medium of the communication from the pneumogastric to the ganglion, impressions passing along which become in it transferred to the inhibitory nerves furnished to the vertebral artery from the ganglion.

Having established this relationship anatomically, it seems impossible to resist observing the analogy between the shock propagated from a contused brachial nerve to the vertebral artery, with its concomitant vertigo, and the lesser shock caused to the nerves of the stomach by the lumps of unchewed meat swallowed by the toothless patient, and propagated thence to the same vessel, and attended with the same condition, viz., giddiness. *Mutatis mutandis*, the cause, the method, and the result are one and the same thing: the experiment is the same, the conditions only are varied. Hence it would seem that Nature had in the labyrinth erected a signal-box, in which a note of warning might be

sounded by the much-abused though tolerant viscus, the stomach, whenever the ill treatment it is subjected to threatens to compromise more vital parts of the organism. It would seem to teach us, what the acquired wisdom of advancing years so often fails to do, that the senile stomach is not the fit receptacle of unmaasticated meat; that it resents the slight shown it in this, and, of course, in many other ways: first of all by the warning attacks of giddiness, which, if not heeded, will shortly culminate in a fall. It was by such a catastrophe that the Duke of Wellington lost his life. The unscathed hero of a hundred fights failed to prove himself master of the situation, when the forces arrayed against him were a vigorous appetite and an acutely sympathetic labyrinthine circulation.

These observations naturally lead us to infer that the doubts which instigated Trousseau to ask himself the question, whether "the treatment which in these cases he directed against the affection of the stomach was not, unknown to him, addressed to the nervous system", were well founded. The fact is it was directed to both. By resting and restoring the digestive apparatus, he appeased those waves of excited vaso-motor sympathy existing between the viscus and the important tissue tracts supplied by the vertebral artery. That these various and distant tissue-tracts are really correlated through the medium of the ganglion in question receives confirmative evidence from the effects of certain drugs. Thus tobacco will produce giddiness, tinnitus, nausea, precordial distress, and *aching in the arms*, amongst other conditions, indicating its progressive influence over the centres of the sympathetic system. Quinine, again, in large doses, produces giddiness, tinnitus, and occasionally, in extreme cinchonism, such trophic changes in the upper extremity that the cuticle will be shed like a glove. Both these drugs, therefore, may be viewed as having a paralysing influence over the inhibition of the lower cervical ganglion. The bromides, and notably hydrobromic acid, have an opposite effect, because they annihilate the aural symptoms of quinine, cure labyrinthine tinnitus; coupled with suitable diet, they remove stomachic vertigo, and have proved highly serviceable in a case of associated hiccough. They have, moreover, a now well established therapeutic relation to epilepsy. But the fact that the treatment of epilepsy, however conducted, is greatly influenced by the diet, that the absolute withdrawal of solid food immensely expedites recovery—a circumstance which I have repeatedly proved—this fact, we say, pointing to a direct influence between the innervation of the stomach and the condition of tone of the vertebral artery, is strongly confirmative of the reality of the correlation advocated in this paper.

From the foregoing remarks, it will be seen that we have, in the infracervical ganglion, an organ for connecting the upper extremities—the heart, the stomach, and upper portions of the digestive apparatus—with the labyrinth. These relationships, in all probability, by no means exhaust its range of influence; but they suffice the objects of this discussion. The ganglion in question brings these widely separated regions into very intimate sympathy by virtue of its regulatory power over the blood-supply of the labyrinth, and of its afferent and efferent branches to the organs referred to. Returning to the case of the toothless patient, who suffered from *vertigo* whenever he partook of solid food, we take the following to be the course of events in this, as probably in all cases of giddiness which originate in the stomach. The ingestion of the irritant gives rise to an impression, which is conveyed along the channel already indicated as forming a communication between the pneumogastric nerve and the infracervical ganglion, whence it is reflected to the vertebral artery in the shape of a wave of diminished inhibition. This is equivalent to an increased flow of blood to the labyrinth, with corresponding pressure on the endolymph. This pressure, physiologically interpreted, means giddiness, so far as it relates to the semicircular canals; and when, as usually happens, the circulation of the cochlea also becomes hyperæmic, there is concomitant tinnitus of a more or less pulsating character. If the vascular dilatation admit of effusion of serum, deafness is superadded; and if the exudation partake of the more solid particles of the blood, so that a clot is formed, the deafness may be permanent. In the milder occurrences, the impression will be transitory, passing away with removal of the exciting cause. It is to be noted that the labyrinth is placed at the extreme periphery of the tract supplied by the vertebral artery; it will, therefore, be the first to appreciate the consequences of the wave of suspended inhibition communicated to it from the ganglion. The phenomena it occasions, under the circumstances, are of such a marked character that they cannot fail of attracting the patient's notice; whether the impression originates in the heart, the upper extremities, or the digestive organs, the first note of warning is thus usually struck in the labyrinth. We are, therefore, justified in regarding this organ as possessing a sentinel like office to warn the subject of changes of blood-supply about to happen throughout the whole of the important regions supplied by the vertebral artery

—such, for instance, as the medulla oblongata and the contiguous nerve-centres at the base of the brain. Hence epilepsy or apoplexy may be about to supervene; the *petit mal* of the former disease being the signal note of the labyrinth, betokening the condition of its circulation, and suggesting the search for sources of suspended nerve inhibition.

In the disturbance of some one or more of the multitudinous sympathies, thus imperfectly sketched, will be found an explanation of the occurrence of those *simple attacks* of labyrinthine vertigo, which come on *without any previously existing ear-disease*, the desire to understand which furnished the key-note of this paper.

## AN EXPERIMENT ON THE DISINFECTION OF ENTERIC EXCRETA.

By JOHN DOUGALL, M.D., F.F.P.S.G.,

Lecturer on *Materia Medica* in the Glasgow Royal Infirmary School of Medicine.

IN the sixth Public Health Report of the Medical Officer of the Privy Council for 1875, is an extremely able account by Dr. Baxter of an experimental study of certain disinfectants. Mr. Simon, in his preface, states that the investigation was carefully planned by Dr. Baxter and Dr. Burdon Sanderson. It may be mentioned that, in the experiments, three infective poisons, viz., that of glanders, that of vaccine, and that of intensified or infective inflammation, were submitted to the action of four alleged disinfectants; viz., permanganate of potash, sulphurous acid, chlorine, and carbolic acid. At the end of the report, the principal inferences which seemed to flow from the results of the investigation are embodied in a series of eleven propositions. In the fourth proposition, it is stated that, "when permanganate of potash is used to disinfect a virulent liquid containing much organic matter, or any compounds capable of decomposing the permanganate, there is no security for the effectual fulfilment of disinfection, short of the presence of undecomposed permanganate in the liquid after all chemical action has had time to subside".

As this conclusion, which is founded on a great number of very interesting experiments, seemed a safe basis for testing further, in an easy and very practical manner, the disinfecting power of the permanganate, I resolved to try its strength in the form of Condyl's fluid with enteric excreta, this fluid being the state in which the permanganate is almost exclusively used by the public. The experiment was conducted as follows. To a newly passed, characteristic, ochrey-looking enteric stool, quantity unknown, a portion of a known quantity of Condyl's fluid was added. The mixture was then stirred and set aside for a short time, and, when the pink colour had changed to a brown, more of the fluid was added, and the process repeated till the pink colour was found permanent after the lapse of twelve hours; in other words, chemical action in the mixture had subsided, as indicated by the presence of the undecomposed pinkish permanganate liquid. The mixture was now measured, and the quantity of Condyl's fluid added being known, this was subtracted from the whole, thus showing the amount of fecal matter acted on. To find the exact relation between the quantity of Condyl's fluid deoxidised and the amount of enteric feces disinfected, was now a simple matter of calculation. Avoiding fractions, it amounted to this (and I confess the result astonished me): one ounce of enteric feces had deoxidised not less than ten ounces of Condyl's fluid; in other words, there is no security that enteric fecal matter is effectually disinfected by Condyl's fluid, unless the bulk of the fluid used be ten times as great as the bulk of the enteric feces to be disinfected. In the same manner, I experimented with a fluid ounce of enteric urine, and here the result was, that one ounce of the urine deoxidised at least two ounces of Condyl's fluid.

Now, supposing a typhoid patient passing twelve ounces of fecal matter and twenty ounces of urine during each twenty-four hours, say for a week, which, it will be conceded, are not excessive quantities, and supposing the Condyl's fluid sold to the public in eight-ounce bottles at one shilling each is used, it follows that two hundred and eighty ounces of Condyl's fluid are required to oxidise or disinfect the week's urine, which, at one shilling per eight ounces, amounts to £1 15s.; and that eight hundred and forty ounces are required to oxidise or disinfect the week's feces, which, at one shilling per eight ounces, amounts to £5 5s.; in all, £7 per week, or at the rate of £364 *per annum*. Supposing a hospital with thirty enteric patients, on an average, constantly under treatment, on these data, it would take £10,920 worth of Condyl's fluid to disinfect their yearly excretions.

## CLINICAL MEMORANDA.

### MOSQUITOES AND FILARIE.

I REQUEST permission to make a correction of a rather serious error that has, not altogether unnaturally, occurred in the annotation that has appeared in the JOURNAL on this subject.

The statement that "the mosquito is the means of spreading the *filaria sanguinolenta* amongst human beings" is absolutely incorrect. It was through the courtesy of the Pathological Society that I was permitted, on the occasion referred to, to combat the error in question, and to explain that the human parasite taken up by the mosquito had no genetic relation whatsoever with *filaria sanguinolenta*.

At the Linnæan Society, on the 7th instant, I communicated the details of Dr. Manson's discovery, originally announced on January 12th. In the discussion that followed, a general acceptance of the correctness of Manson's views was accorded by Dr. Allen Thomson, Sir Joseph Fayrer, Mr. Curling, Mr. Ray Lankester, Dr. Collingwood, and also by Mr. MacLachlan, the well-known entomologist. The President of the British Association acknowledged, for his part, that he thought that the authors of the two papers before the Society had fairly proved their case; and Sir Joseph Fayrer characterised the subject as one of unparalleled interest and importance in relation to public health in the tropics.

If there were one point more than another upon which I insisted at the Pathological Society, it was on the necessity of not mixing up the *filaria sanguinolenta*—an entozoon of the dog, known to Redi nearly two centuries ago—with the *filaria sanguinis hominis* of Lewis, the *filaria immitis* of Leidy, and the *hematozoon subulatum* of Leislering. Unfortunately, as if the nomenclature of these helminths were not already sufficiently complicated, we have Dr. Beale giving the weight of his great authority as a microscopist to an error which I felt it my duty to expose on the night in question, and which, I regret to see, has now even gained the sanction of the valued columns of the JOURNAL. In the last page of the fourth edition of the *Microscope in Medicine*, the author writes as follows: "Dr. Cobbold seems not to be aware that, in his work on *The Pathological Significance of Nematode Hematozoa*, published in 1874, Dr. Lewis gives an account of the mature '*filaria sanguinolenta*, with drawings of the male as well as of the female worm.'" If anyone will read the context in Dr. Beale's work (p. 505), they will at once perceive that Dr. Beale's object is to defend Lewis's position on the question of priority in reference to the discovery of the sexually mature worm. Dr. Beale's imagination has led him to fancy that the *filaria sanguinolenta* is the same worm as Lewis's *filaria sanguinis hominis* and my *filaria Bancrofti*; and then he has sought to make it appear that I am ignorant of Lewis's memoir—a little work a copy of which was sent to me by the distinguished author himself, and which, I may add, is scarcely ever out of my sight.

The members of the Pathological Society will testify to the earnestness of the appeal I made in reference to the necessity of precision and accuracy in dealing with the numerous forms of hematozoa of man and animals. The number of errors that have been published on this head is very considerable. I do not allude to mere questions of microscopic size and so forth, concerning which all of us are liable to err; but when it comes to the confusing of species which have absolutely no connection with one another, and not even any relation as regards their bearers, then I feel it is impossible to remain silent.

T. SPENCER COBBOLD, M.D., F.R.S.

### THE ACTION OF OPIUM AND ATROPIA.

THE publication in the JOURNAL of the case of opium-poisoning successfully treated by atropine, and Dr. John Harley's letter of warning, induce me to send a brief account of a case in which the physiological action of these drugs received a *vice versa* illustration.

Early one morning in November last, shortly after midnight, I was summoned out to a lady who had been seized with angina pectoris, of which complaint she had had several attacks during the past few months. On my arrival, I found her sitting up in bed, with her head and body bent forward between her knees, in agonies of pain; the extremities cold, the pulse feeble, and the pupils dilated. She had also frequent retching, and was incessantly pushing forward her tongue and asking for "water, water". I was told she had vomited several times; but what she had thrown up last had alone been kept, and I found this to consist merely of bile and mucus without any peculiar smell. Having brought with me my hypodermic syringe and a solution of morphia, I gave her at once an injection of about a quarter of a grain of morphia. Almost immediately the pain and retching ceased, the

sensation of thirst diminished, and soon afterwards my patient fell asleep. Fearing lest there should be a return of the angina as soon as she awoke, I thought it a favourable opportunity to go to my house for a supply of nitrite of amyl, as I had omitted to bring some with me. On my return, the friends met me looking greatly alarmed; and, when I entered the sick-room, I must own I was myself somewhat frightened, for I found my patient looking ghastly pale and her breathing rather shallow. However, when I placed my finger on her pulse, I found it beating strongly and regularly. The limbs were warm, and the pupils but slightly contracted. I then assured them she was only sleeping; and in a few minutes she awoke with a deep sigh, when I at once administered some brandy. I now learned that, previously to sending for me, this lady had been given at the commencement of the paroxysm of angina, at her earnest entreaties, dose after dose of a mixture I had prescribed for her about a month before, as she had found it to relieve her on former occasions, and sometimes to ward off an attack. The mixture contained five minims of liquor arsenicalis and a minim and a half of liquor atropiæ (*B. P.*) in each dose; and, fortunately for my patient, there were not quite four doses in the bottle at the time when her friends so foolishly yielded to her urgent solicitations, or the result might have been different. She had thus taken nearly twenty minims of liquor arsenicalis, and nearly one-twentieth of a grain of atropia; but, as she could not at any time take more than one dose of the mixture in the twenty-four hours without the atropia causing dryness of the mouth and throat, on this occasion all the physiological symptoms of atropia-poisoning were present to a greater extent than one would be led to expect where so small a quantity of atropia had been taken. The Fowler's solution did not seem to have produced any bad effect, as there was no coryza, cramp, or diarrhoea. I should also mention that the solution of morphia I used contains a small quantity of atropia as well (forty-five minims of the liquor atropiæ in the ounce); but, as only one-eighth of a minim, or 1-320th of a grain, of atropia was given subcutaneously, it is not worth taking into consideration. It was some days before the dryness of the tongue and throat passed away, and shortly afterwards a severe attack of gastritis followed. CHRISTOPHER ELLIOTT, M.D.,  
Physician to the Bristol Children's Hospital.

## THERAPEUTIC MEMORANDA.

### DIALYSED IRON.

"DIALYSED iron" is the name given to a preparation recently introduced, which, judging from the frequency with which it is advertised, must be meeting with considerable favour. Now, to begin with, if "dialysed" means "that which has passed through a dialyser", it is not dialysed at all, as it consists of a solution of the colloid hydrated ferric oxide, which remains behind in the dialyser, being incapable of diffusing through organic membranes. This being the case, it is of course quite incapable of absorption; only the very minute portion dissolved in the gastric juice can be taken up, and consequently the preparation is practically inert. French physicians have already taken this view of it; but its true use seems to have been apprehended in America—viz., as a ready source of hydrated ferric oxide in poisoning by arsenic. JOHN CAVAFY, Upper Berkeley Street.

### THERAPEUTIC USE OF IODOFORM.

A. B., AGED 40, mother of six children, caught typhoid fever after nursing a daughter through a very bad attack of the same disease. When she was recovering, a large oval ulcer appeared on the inner aspect of the left thigh; and ten days afterwards a number of vesicles appeared all over the body. These soon assumed the appearance of rupia. I then questioned the husband as to the possibility of syphilis; but he denied having had anything of the kind. (I have since had reason to doubt his veracity.) Yet his wife became absolutely covered with large conical scabs, with inflamed ulcerating bases. I now tested the case by treatment, and simply added iodide of potassium to her medicine. As there was a slight improvement, I asked Mr. McCheane, Surgeon to the Liverpool Lock Hospital, to see the case for me; but he also felt some difficulty in deciding whether it was syphilis or not (on account of the family history), but advised iodoform ointment (5i to 3i), and to continue the iodide of potassium. The improvement was so marked that I added iodoform in pills, containing each one grain, three times a day. In four days, healthy granulations made their appearance; large excavated ulcers filled up and rapidly healed, leaving only slightly depressed scars. I commenced the iodoform on

January 28th, when the body was covered with frightful-looking ulcers, ten being on the face alone, three on the throat; the nose almost destroyed. On February 21st, only a few sores on the legs remained unhealed. D. M. WILLIAMS, Liverpool.

### KOUMISS IN OBSTINATE VOMITING.

Miss L. G., a young lady, aged 17, having suffered from anæmia for some time, constant vomiting set in as the result of gastric catarrh. Nourishment of any kind was rejected as soon as taken; and I think I may safely say that all the remedies recommended in such cases were tried without producing any good effect. The patient was kept alive by nutrient enemata. After this condition had continued for a fortnight, I ordered the patient to try koumiss No. 1. Wineglassful-doses were given every half-hour at first, and the quantity gradually increased. At the end of the third day, the sickness had ceased. Twenty four ounces were now taken in the twenty-four hours; and for three weeks this formed the entire nourishment of the patient. On one occasion during this period, the supply ran short for one day. Milk and soda-water and milk and lime-water were substituted, but were at once rejected. When the stomach seemed to have recovered a little tone, small quantities of fresh milk were added to the koumiss, and in time Miss G. was able to take light nourishment in other forms, and improved steadily, the koumiss being gradually given up.

About three months afterwards, the vomiting and other symptoms returned. All remedies failing, koumiss was again resorted to, and without any other treatment the sickness lessened, and finally disappeared. Fresh milk was then carefully added, with five grains of lacto-peptine to five ounces of the milk. At this date, the patient is steadily improving. No koumiss has now been taken for six weeks, and there has been no return of the vomiting.

My experience of koumiss treatment has been limited to this case; but as it afforded scope for a fair trial, I have reported it at some length. I shall certainly resort to koumiss again in suitable cases with much confidence, its feeding and curative powers having exceeded my expectations.

NORMAN MCCASKIE, M.B., C.M.Edin., Great Ouseburn.

### BLACK WASH PRODUCING PTYALISM.

IN January last, I had an elderly gentleman under my care for eczema of the scrotum and penis, accompanied with prurigo senilis and a copious eruption of urticaria. After the irritation of the scrotum had somewhat subsided, I prescribed a lotion composed of one drachm of calomel, an equal quantity of carbolic acid, and lime-water to eight ounces. He was progressing favourably, when, strange to say, in a few days, the system became mercurialised, as evidenced by fetor of the breath, tenderness and swelling of the gums, etc. The result was unfortunate, as an exacerbation of the eczematous eruption occurred; and the patient, becoming dissatisfied, suddenly left Dublin for his home in the North of Ireland.

That this gentleman's constitution was peculiar was also shown by the effect scruple doses of hydrate of chloral (Liebreich's) produced, causing considerable excitement, accompanied with delusions on more than one occasion.

C. H. ROBINSON, F.R.C.S.I., Lecturer on Anatomy,  
Ledwich School of Medicine, Dublin.

### THE TREATMENT OF BROMIDE OF POTASSIUM ERUPTIONS.

THE discussion which took place in January, at the London Pathological Society, on bromide of potassium eruptions, having aroused considerable interest in them, and the possibility of their occurrence in cases in which it would be particularly undesirable to suspend the administration of the bromide, have appeared to me sufficient excuse for this note.

The patient, a young woman aged 22, under my care in the outpatient department of the Cumberland Infirmary, was being treated for epilepsy with drachm-doses of bromide of potassium three times a day. As the fits persisted, although lessened in frequency, the dose was increased to eighty grains. Soon after this increase, a pustular eruption, scattered generally over the body and extremities, and of which the patient complained much, began to appear. The bromide was stopped for a time and the eruption disappeared; but the increase in the frequency of the fits made it imperative to resume the remedy. This was done and the larger dose given, and again the eruption appeared. As it is a well known fact that arsenic counteracts the earlier physiological

action of the iodine compounds, at least in a certain proportion of cases, I ordered five minims of liquor arsenicalis to each dose of the bromide. Within a week, the eruption had gone, and no fresh papules appeared. The eruption was first papular, then pustular. None of the pustules were smaller than a good sized dried pea, and the largest were double that size; there was a zone of inflammation round their bases.

Of course, one such case proves nothing; but, in the absence of any more definite knowledge, similar treatment might be worthy of trial when these comparatively rare cases come under our notice.

WILLIAM RUSSELL, M.B. Edin., Carlisle.

#### SIX CASES OF RHEUMATIC FEVER TREATED SUCCESSFULLY BY SALICINE.

I HAD almost come to the conclusion, from my own experience of the usefulness of salicine in rheumatism, and from what I had hitherto seen recorded, that salicine and its salts had fairly established their claims as a medicine requiring at our hands a fair trial in all cases of rheumatism. As, however, I have observed during the past few weeks reports of some cases unfavourable to it, I think it due to the profession to place on record my observations on the use of salicine.

CASE I.—Eighteen months since, I was called upon to visit J. D., aged 35, a labourer, who had just come from England with his family. He was very ill of acute rheumatism, nearly all the large joints of his body being implicated, with considerable swelling. As I had no salicine, I gave alkalies until it was procured. On the fifth day from the first visit, there was no amelioration of the symptoms; the patient was rather worse. I ordered ten grains of salicine every third hour. Next day (6th), there was no improvement; he complained of pain in the cardiac region. I ordered a large sinapism to the cardiac region and the treatment to be continued (salicine and no stimulating diet). Next day, he was considerably improved. On the third day from commencing salicine, the pains were almost gone. On the fifth day, the salicine was discontinued, as all pain had entirely disappeared, the patient feeling comparatively well, only a little weak. I ordered quinine and iron. Four or five days afterwards, J. D. had a slight relapse, owing to injudicious exposure to cold, which a few doses of salicine again removed, when my patient made a steady and rapid recovery.

CASE II.—G. W., aged 45, a cabinet-maker in search of work, had tramped from Dublin. On my first visit, I found this patient very low, having been ill some time, and in a state of great depression. He refused to go to hospital. He had considerable pain and swelling in all the joints of the lower extremities. Quinine and iron, alkalies, and cotton-wool were of no avail. In the course of ten days, I resorted to salicine in the same doses as in Case I. Great relief was obtained on the third day. The salicine was continued in smaller doses for other three days, when the pains were all gone. He made a steady convalescence under quinine and iron.

CASE III.—J. N., aged 25, a carter, was found at my first visit suffering from a very severe attack of rheumatic fever, with comparatively little swelling of the joints. I ordered alkalies for a day or two; but, the patient growing worse, I gave salicine on the third day in the same dose as the other cases. On the fifth day, he was much improved; his progress towards recovery was steady and uninterrupted. The after-treatment consisted of iodide of potassium and infusion of quassia.

CASES IV and V were ordinary attacks of rheumatism, occurring in adults. Salicine was given with considerable relief after the first twenty-four hours. On the third day, the pains had altogether gone. Both cases made good recoveries under quinine and iron.

CASE VI.—C. Q., aged 38, a washerwoman, living in the country, was found at my first visit suffering from an attack of rheumatism of moderate severity. I gave her alkalies. On the tenth day, the pains having considerably subsided, she left her bed and returned to her occupation at the tub. On the following day, the pains returned with considerable severity. I now gave salicine in the usual dose. Relief was obtained, as in Cases IV and V. She neglected to come for the medicine for two days, and the pains somewhat returned. She was again placed under salicine. Her recovery was steady and complete. No after-treatment was adopted.

In Cases I and VI, there is confirmatory evidence, as it were, of the great benefit to be derived from the use of salicine in these cases, as in both, the medicine having been discontinued, injudicious exposure caused a return of the malady, to be at once benefited by salicine. In Case I, although cardiac symptoms supervened, I continued treatment, only ordering a large sinapism, although my non-experience of this drug might have guided me otherwise. Can salicine do more than relieve the pain? My observations on these cases point to this drug

having fulfilled its mission when all pain ceased. Then we are to look to our old landmarks to complete the rehabilitation of our patient. In Case I, I look upon salicine as having saved my patient from a severe cardiac attack. This medicine is, I think, likely to be highly beneficial in preventing complications, as it seems to act directly on that powerful factor, pain, thereby cutting short the attack by altering, in some way or other, the composition of this peculiar poison, and hastening its elimination from the system.

JOHN MARTIN, L.R.C.P.I., L.R.C.S.I.,

Senior Medical Attendant, Belfast Dispensary.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### CONSULTATIONS.

FEBRUARY 14TH.—*Congenital Deformity of the Lower Extremity.*—A little girl, aged 9, was exhibited before the surgical staff. She suffered from a remarkable malformation. The left leg was much shorter than the right, atrophied and dislocated outwards on the femur, the inner condyle of which bone had grown perceptibly since she had been under medical observation; there was talipes equino-varus of the left foot. Her mother positively asserted that, when three months pregnant with this child, she was much affected by seeing a man with a crippled leg. The child was born with the leg dislocated, but the deformity had much increased as she grew up.—Mr. LANGTON, who brought forward the patient in the absence of Mr. T. Smith, believed that the tibia was quite absent in the deformed limb. He advocated amputation.—Most of the surgeons recommended that operation; but Mr. CALLENDER, bearing in mind the slight risk always attendant on such operations of expediency, suggested that an apparatus might be applied, which would not only serve for locomotion, but also pack up the deformed leg and protect it from injury.

February 28th.—*Congenital Perineal Tumour.*—A male infant, over three months old, was shown, in the operating theatre, by Mr. T. SMITH. A large, round, soft tumour projected from the perineum; it was covered by smooth healthy skin; from its anterior part there projected a tongue of corrugated integument, resembling a prepuce, and about a quarter of an inch in length; from the back of the tumour grew another but smaller cutaneous appendage. The whole looked like a second set of external organs of generation; the tumour was larger than the true scrotum. Mr. Smith found, on examining the growth by palpation, that it contained a rod-like body feeling like cartilage. The swelling was attached to the perineum, close to the left bony boundary of that region; it did not appear to have deep connections.—All the surgeons present were in favour of its removal, which Mr. Smith forthwith decided upon.

*Tumour in the Left Iliac Fossa.*—Dr. SOUTHEY solicited the opinion of the surgical staff upon the case of a middle-aged labouring man. Three years previously, the man noticed an odd persistent sensation, as though some fluid were dripping into the left testicle; at the same time, his gait became unsteady. A lump gradually formed in the left iliac fossa, and he experienced partial intestinal obstruction. At present, a distinct pulsating swelling could readily be detected by palpation. Dr. Southey believed that there was a tumour in the iliac fossa pushing the external iliac artery forwards, pressing backwards on the sigmoid flexure and on the large nerves around it; this would account for all the symptoms.—After a long and careful examination by the whole of the staff present, Dr. BLACK expressed his belief that a bony tumour existed.—All the surgeons detected masses of scybala, and some were of opinion that there was a new growth as well, but nothing could be decided till the large intestine had been thoroughly washed out by enemata.—Mr. MARSH had seen a case where a similar swelling had been detected in the iliac fossa, and found to be an abscess, bound down by the iliac fascia and surrounded by indurated tissue.—Dr. SOUTHEY declared his intention of submitting the patient once more to examination after the scybala had been cleared by injections.

*Results of Pressure on Facial and Trigeminal Nerves.*—Mr. SAVORY begged his colleagues to examine at their leisure a remarkable case in Abernethy ward. A young Irish labourer, aged 21, had been subject

to glandular swellings behind the angle of the jaw on the right side, extending over the sterno-mastoid muscle. They were now very firm, increasing slowly, well circumscribed, and free under the integument, which was healthy and not red. Six months before admission, the right eye inflamed; it had been quite blind for six weeks, and the cornea had sloughed. There was deficient sensation of the skin of the right side of the face, and facial palsy on the same side without ptosis; the inability to close the right eye was very marked. The patient could not hear a watch placed against the pinna of the right ear. That the glandular swellings extended deeply behind the jaw there could be no doubt; pressing on the facial and trigeminal nerves, they had produced results already recognised by physiologists through experimental proof.

## ST. GEORGE'S HOSPITAL.

### DR. DICKINSON'S WARDS.

*Hydronephrosis.*—A married woman aged 26 was admitted to hospital complaining of an abdominal tumour, tender and painful. Seven years previously, she had a natural confinement; but from that time she dated her present illness; she had never been well and strong since. Five months after that confinement, she was suddenly attacked with pain in the right lumbar region, headache, and vomiting; and, after this, she for the first time became aware of a tumour at the seat of pain. She had since been troubled with similar attacks of pain returning at intervals of three or four months; lately, they had been more frequent. For two or three days before each attack, she usually noticed that the urine was high coloured, while, during the attack, it was natural in appearance. During the seven years of illness, she had had two miscarriages, proving that the disease, whatever it might be, had not prevented pregnancy. Menstruation had continued regular. For a week previous to admission, she was laid up with continuous abdominal pain. The woman was an in-patient last year, and then a rounded mass, of the size and shape of an adult kidney, was felt in the right lumbar region, and was movable; the urine was then highly albuminous. While in hospital, the tumour diminished in size; and, when discharged, she was quite free from pain. At the present time, a rounded tumour, at least eight inches in diameter, is felt in the right lumbar region, extending forward almost to the umbilicus. It is tender on pressure, and indistinct fluctuation can be felt. Dr. Dickinson considered that the tumour was probably a renal cyst, though the possibility of ovarian disease was not omitted from consideration. There was no history of a calculus or gravel having been passed; but the presence of blood in the urine, the intermittent character of the attacks of pain, and the partial subsidence of the tumour when previously in hospital, afforded evidence in favour of hydronephrosis. It was also pointed out that a tympanitic note was obtained on percussion over the anterior portion of the tumour, owing to its being overlapped by the colon, as is usual with renal tumours. The tumour could be well isolated from the liver. It has lately remained stationary in size, and the patient's general health has remained good throughout, thus excluding the idea of cancerous growth. There has never been a sudden subsidence of the tumour, as is sometimes the case with hydronephrosis.

*Perityphlitis.*—A healthy looking and fairly robust young woman had been quite well, but for a slight catarrh of a month's duration, till eight days previously to admission, when she was attacked at night with diarrhoea and vomiting. The next day, she suffered much abdominal pain; the bowels were costive, and she had completely lost her appetite. There were no rigors or sweats, and the pain subsided at the end of a week. On admission to the hospital, she complained of pain in the right iliac region, increased by deep inspiration, but unaffected by taking food. There was no other pain, and no nausea. She did not appear ill but for the local trouble; the bowels were confined; menstruation was natural. A distinct swelling was felt in the region of the caecum, which was tender on pressure; there was no sign of mischief in the pelvis. Dr. Dickinson remarked that, though such cases are not unfrequently met with, their pathology is not exactly known, as they seldom die. This condition is met with both in men and women; it generally commences with disturbance of the bowels and griping, and appears to commence in inflammation of the caecum. In this case, the temperature never rose above 100 deg. Fahr., and there was no sign of suppuration. Leeches were applied, followed by poultices. A mixture, containing ten minims of tincture of opium to the dose, was ordered to be taken every six hours. Aperients are here inadvisable.

*Salicylate of Soda in Acute Rheumatism.*—In cases of acute rheumatism, Dr. Dickinson usually prescribes salicylate of soda in doses of about fifteen grains, with four scruples of bicarbonate of potash, every

four hours, taking care thus to keep the urine distinctly alkaline. The advantages of the salicylate are thus obtained, and, under this plan of treatment, cardiac complications have been less frequently met with than under the simple alkaline treatment. Many cases have, however, relapsed, and some have subsequently developed cardiac bruits.

*Chronic Bright's Disease.*—A woman aged 25 was admitted to the hospital, on account of albuminuria. There was no history of any hereditary disease in her family; she had been fairly robust, and had not suffered from any previous illness. During last year, she worked in a shop through long hours, much exposed to draughts. Two months ago, she noticed slight swelling of the feet at night; her appetite became defective, and she was troubled with dyspnoea. Three weeks before admission, she was obliged to leave her work, on account of failing strength. Menstruation had continued regular. Physical examination showed signs of cardiac hypertrophy; the heart's apex was slightly displaced to the left of its normal position; the impulse was strong and the sounds distinct, especially the first, which was slightly prolonged at the apex; the second sound was also accentuated; the tension in the radial pulse was high, considerable pressure being required to obliterate it. The quantity of urine was not increased, but it contained a trace of albumen. From the high state of arterial tension, the trace of albumen in the urine, and the almost total absence of dropsy, it appeared probable that the kidneys in this case might be undergoing granular contraction.

*Malignant Disease of Cranial Bones.*—A lad aged 17 was admitted on account of convulsive seizures, probably dependent on intracranial malignant disease. Nearly two years ago, he was a patient in the surgical wards, and a malignant growth of the superior maxilla was then removed. Some months ago, he became liable to epileptic seizures, each lasting about a minute; usually two or three occurred in succession at intervals of from two days to two months. In these attacks, he never completely lost consciousness; he was able to give a warning of the approach of an attack, and said he then felt "as if something rose out of his stomach". He complained much of headache, which he constantly referred to his left parietal bone; he frequently vomited after his food. No disease of the cranium could be found on external examination. The liver appeared normal. While under observation, he one day had two convulsions closely following one another; each lasted about three minutes. The right side was first convulsed, then the left; there was hardly any period of complete unconsciousness. He has been kept quiet and taken bromide of potassium; the fits have become less severe, and the headache has gone. It appears probable that malignant disease is returning within the cranium. There is no optic neuritis.

*Chronic Empyema.*—A woman aged 35 had suffered with pulmonary symptoms three or four years. She complained of languid feeling, loss of appetite, cough occasionally troublesome, and profuse night-sweats; she had also noticed for eighteen months epigastric pulsation. When admitted to hospital (August 1877), she was very weak, and complained of weakness, cough, dyspnoea, and abundant muco-purulent expectoration. The left chest was completely dull, back and front; the respiratory sounds were very faint and sibilant; the heart was felt beating to the right of the sternum. The right side of the chest was apparently healthy. An experimental puncture into the left chest was made with a hypodermic syringe, and pus was withdrawn. She was then aspirated, and twelve ounces of pus were withdrawn. The patient remained in the hospital till December, and was aspirated in all five times, pus being withdrawn each time in quantities from twelve to forty ounces. When discharged, she was free from all pain and dyspnoea. When readmitted in February of the present year, she again complained of troublesome cough, deep-coloured rusty sputum, and loss of flesh. There were also faintness on any exertion, and abundant expectoration of mucopurulent matter. There were signs of bronchitis in the right lung, and the left pleura appeared full of pus as before; it was not, however, as large as before, measuring in circumference only thirteen inches and a half on the left side, against fourteen and a half on the right. The presence of pus being again proved by the hypodermic syringe, the aspirator was used, and eighteen ounces of pus were drawn off. Since this, she has been free of cough. Dr. Dickinson proposes, as the pleural cavity is smaller than it was, to make a permanent fistula and let the pus drain away.

### MR. ROUSE'S WARDS.

*A Calculus impacted in the Urethra.*—A man aged 40 was admitted into the hospital, on account of perineal fistulae. When he was eleven years of age, a perineal abscess formed and burst; it soon healed. Seven years ago, an abscess again appeared in the same situation and discharged for two years; at this time, there were difficulty and pain on micturition. Three years ago, the abscess again formed and burst; there was

swelling of the penis, scrotum, and whole perineum. Several abscesses occurred; they discharged and left sinuses; there was difficulty on micturition, and the urine began to come away through the sinuses. Eighteen months ago, a surgeon attempted to pass a catheter, but failed, and, since that time, the urine has dribbled from him constantly. When admitted, his scrotum and the parts about the pubis were oedematous and indurated; the perineum was also indurated, and this condition extended on each side to the buttocks. He had complete incontinence of urine. A catheter could not be passed beyond the bulbous urethra; the finger in the rectum felt a very large hard mass in the situation of the prostate, projecting backwards into the rectum; above, it extended so high that the index-finger could not reach its upper limit. This examination caused blood to pass by the urethra. A few days later, the patient was placed under the influence of ether. The prepuce being long and oedematous, and rendering it impossible to see the meatus, it was slit up. A catheter could not be passed beyond the os pubis, where it was arrested by an apparently dense, rugged, cartilaginous mass. A free incision was then made through the oedematous perineum on to the urethra; the finger, passed to a considerable depth, felt in the centre of the perineum a mass harder than the rest; on careful examination, this proved to be a calculus lodged in a dilated portion of the urethra. This was removed with forceps, and was found to be a small uric acid calculus surrounded with much phosphatic deposit. After its removal, there was no difficulty in passing a catheter into the bladder. The seat of the calculus in the urethra was felt to be hard and cartilaginous. A gum catheter was tied in. Since the operation, the general swelling has much diminished, and the patient is progressing favourably.

*Lithotomy.*—The patient was a boy aged 14. When he was four years old, some operation was performed for the removal of a stone from his bladder. Since that time, the bulk of his urine had passed through the anus and only occasionally by the urethra. During the last two years, he had at times had great pain at stool, with straining, and had sometimes passed blood with his motions, but had never passed blood by the urethra. On examination, a small cicatrix, half an inch in length, was seen a little to the left of the anus, running right up to the mucous surface of the rectum. By using a speculum, a small rounded opening, a quarter of an inch in diameter, was seen in the anterior wall of the rectum, and urine dribbled from it. A sound in the bladder detected a stone, and, with a little difficulty, it was passed through the opening into the rectum.

A month ago, Mr. Rouse performed lateral lithotomy in the usual manner. A large stone was found encysted behind the public portion of the bladder; and, with some little difficulty, it was removed in several pieces. It was for the most part soft phosphatic deposit, with a hard uric acid nucleus; probably the complete calculus was about the size of a small walnut. After the lithotomy, a duck-bill speculum was introduced into the rectum; the edges of the fistula were pared, and brought together with silver sutures without difficulty. A lithotomy-tube was tied in the perineal wound. The wound and fistula are now healed, and the patient is convalescent.

## ST. JOHN'S HOSPITAL FOR SKIN-DISEASES.

### CASES OF LUPUS AND RINGWORM.

(Under the care of Mr. JAMES STARTIN.)

*CASE I. Lupus.* J. S., a young woman aged 18, living in London, was admitted into the hospital in June last, as an in-patient, under the care of Mr. James Startin, suffering from an inflamed irritable sore on the right cheek, about two inches broad by three long, of an irregular oval shape, with excavated edges. The surface of the sore was covered with yellow and greenish crusts, and on the exposed intervals a low form of granulation-tissue was seen, freely discharging. The patient said that the sore began as a small isolated inflamed pimple, when she was about seven years old, and that it had gradually spread and ulcerated up to the time of her admission. It was accompanied with a creeping and sometimes acute pain. The outer angle of the eyelid on the side affected was drawn considerably downwards and outwards. She appeared a healthy well-nourished girl, with a clear fine skin, usually diagnostic of a scrofulous tendency. The patient stated that she had applied to several hospitals, with little or no relief.

June 11th. The patient was ordered cod-liver oil twice a day, and a mixture of iodide of potassium and Donovan's solution three times a day. The sore was dressed with a caustic arsenical paste, and the whole covered with flexile collodion, which latter was used twice a day for three weeks.

July 30th. The sore now appeared much diminished in size, and the granulations more healthy. She became an out-patient, and was

ordered a lotion containing two grains of bichloride of mercury to the ounce.

In September, the sore had decreased to the size of a shilling; it was touched with a solution of nitrate of mercury, and the cod-liver oil and tonics were continued.

This patient is now quite well, and the sore has healed, leaving only a small quantity of cicatricial tissue, and the eyelid has resumed its normal position.

*CASE II. Lupus.* M. W., residing in the neighbourhood of Reading, age 33, applied at the hospital for advice, in October last. He was a tall, fine healthy-looking man, but suffered from an erythematous eruption on the left side of the face, extending from the inner angle of the eye to the lobe of the ear and upon the side of the neck. The outer angle of the eyelid was considerably detracted in this case. The patient stated he was under the late Mr. Startin's care about fifteen years ago, at which time the disease was much worse and was ulcerated; and that he very nearly recovered until the last two years, when it again broke out in the above form. Mr. Startin ordered him large doses of cod-liver oil and a mixture of iodide of potassium, and occasionally applied the mercurial caustic.

*REMARKS.*—These cases of lupus seem to have yielded to continuous doses of cod-liver oil and alteratives, combined with a cautious use of caustics, being also completely excluded from the septic influences of air-germs and currents by collodion, which is not the least important part of the treatment in these cases, and which, Mr. Startin believes, has not as yet been tried, nor is it mentioned in any cutaneous work.

*CASE III. Ringworm.* H. K. came to the hospital in February last, and under Mr. James Startin's care in May. By the parents' statement, the patient had suffered from ringworm for nearly three years, caught at school. The disease manifested itself in a dry circumscribed scurfy patch, three inches in diameter, on the posterior and upper part of the head, over the occipital and parietal bones. The hair was cut short, and, upon close inspection with a powerful magnifying glass, seemed to have broken or torn off about a line or so from its exit from the epidermis. There was a slight itching in the part, and the hair appeared dull and brittle; and, upon microscopical examination, after soaking a piece of the skin, with its adherent hairs, in a solution of liquor potassæ, the hairs were seen to be split up and largely invested with numerous bundles of conidia of the trichophyton tonsurans, or vegetable parasite of the hair. These short, dull broken hairs were shown to be the true characteristic of the disease to the naked eye; and it must also be borne in mind that no crusts, discharge, pustules, or pimples accompany the true form of ringworm—indeed, their presence would only indicate some other cutaneous disease. The patient was ordered large doses of cod-liver oil, with occasional local applications, and sent into the country. Mr. Startin saw him in June and July, and again in September, when he was quite cured, and was passed by the medical officer of one of the large metropolitan public schools and admitted as quite free from the disease.

*CASE IV. Tinea.* F. W., aged 7, applied to the hospital in July last, suffering from three or four patches of tinea tonsurans and one or two of tinea circinata upon the back and shoulders, evidently contracted from the head-affection. His parents stated he had caught the disease at school, and had had it about a year. The treatment was much the same in this case as the last. The patient was discharged cured in November.

*CASE V. Tinea Tonsurans.* Three children, aged respectively 8, 6, and 14, came as out-patients under Mr. Startin's care, suffering from tinea tonsurans, early in June. The mother said the eldest child caught the malady at school two years ago, the second and third eighteen months ago. They were discharged cured.

*Treatment.*—The treatment which Mr. Startin finds in these cases to be successful and rapid, and to prevent the spread of the disease, consists of: 1. Complete isolation of the patient; 2. Disinfecting and boiling all brushes, towels, etc.; 3. Disinfection of the rooms occupied with burnt sulphur; 4. Great attention to cleanliness and diet. The ill-fed should be well nourished, and any deficiency in food should be made up by the administration of cod-liver oil and iron. The head should be daily washed with yolk of egg and warm-water, keeping the hair cut short at and for a short space round the diseased patches; and the part should be occasionally dressed with some oleaginous preparation containing a parasiticide, viz., oil of cade or tar, sulphurous acid, and iodine, with a daily application of a stimulating mercurial ointment.

The question is often asked: "Is the child cured, and when may he return to school?" The following rule seems to be the safest and best. So long as any trace of the fulfuraceous patches remains upon the head, showing dull broken hairs, with their minute vegetable organisms, on careful microscopical examination, the child must not be allowed to return to school.

## LIVERPOOL ROYAL INFIRMARY.

## CASES OF HERNIA.

(Under the care of Mr. REGINALD HARRISON.)

**CASE I.—Strangulated Inguinal Hernia: Operation, followed by violent Delirium: Recovery.**—J. L., AGED 38, a publican, was admitted into the Liverpool Royal Infirmary on November 9th, 1877, suffering from an irreducible inguinal hernia. The patient appeared to have been ruptured for twelve months previously, and had worn a truss. On November 6th, believing his rupture to be cured, he left off the truss. He was at this time suffering from chronic bronchitis. On the night of the 6th, whilst coughing, the hernia descended, and all attempts made to reduce it were futile.

On his admission, the symptoms of obstruction were not urgent, and for twelve hours, opiates and ice applied to the tumour, were tried.

On the 10th, as the symptoms of strangulation were more marked, Mr. Harrison operated. On opening the sac, a piece of omentum, but no bowel, was found tightly strangulated, but not in such a condition as to preclude its being returned into the abdomen. The absence of intestine explained the slow development of urgent symptoms of strangulation which marked the history of this case. Having regard to the patient's occupation, morphia and a moderate quantity of stimulant were prescribed.

On the evening of the 14th, he became most violently delirious. The excitement was so intense that Dr. Knox, the house-surgeon, thought it necessary to give him chloroform, under the influence of which he was kept during almost the whole of the night. The sleep thus obtained was followed by marked improvement, as on the next day the patient was able to take a fair quantity of fluid food and stimulants. He was also given a mixture containing morphia and bromide of potassium, which appeared to prevent the development of any further symptoms of excitement.

The patient left the Infirmary quite recovered on December 5th.

**CASE II.—Strangulated Femoral Hernia: Operation: Recovery.**—In the following case, the very unusual accident of the hernia-knife snapping as the stricture was being divided occurred.

A. Y., aged 49, a widow, was admitted on December 30th, 1877, with a strangulated femoral hernia. The patient had suffered from hernia for three years. Four days before admission, a very considerable protrusion took place on the patient making an usual effort to carry a heavy weight. Reduction was attempted, but without success.

On admission into the Infirmary, the symptoms of strangulation were urgent. Mr. Harrison at once proceeded to operate. On opening the sac, the intestine was found of a deep claret colour. The stricture was unusually tight. As the hernia-knife was in the act of dividing the stricture, Mr. Harrison felt it snap upon his finger about the centre of the cutting edge. With difficulty he succeeded in retaining hold of the portion that had broken off, and removing it with a pair of forceps. Before returning the intestine into the abdomen, it was withdrawn from the canal and carefully examined, for the purpose of seeing whether it had received any damage during the manipulation necessary to extract the broken blade. A small puncture was found in the bowel, which had evidently been caused by the abrupt angle of the knife where it had given way. This opening Mr. Harrison was able to include within the teeth of an artery-forceps; it was then closed by means of a noose of fine carbolised catgut. The intestines were returned into the abdomen, and the wound in the skin closed by wire sutures. The patient was put under the influence of opium administered by small enemata.

On the fifth day after the operation, the bowels acted spontaneously. The patient made a good recovery, and returned home on January 24th, 1878.

In commenting upon the very unusual nature of the accident that occurred during the operation, Mr. Harrison said that he had no explanation to offer as to the breaking of the knife. It was an instrument which he had frequently used on other occasions, and was in this instance specially selected as soon as the extremely tight nature of the stricture was discovered. No flaw was observable in it. As the broken portion was only supported by the tip of his index finger, it was with the greatest difficulty prevented from falling within the abdomen, and so considerably adding to the danger of the complication. The case further illustrated the great value of the catgut ligature in the case of small punctured and incised wounds of the intestine, where such can be included in the noose. Mr. Harrison considered that the case should be recorded as illustrating the very unexpected contingencies that may arise in the course of an operation, and where every provision against accident has been taken.

## ST. MARK'S OPHTHALMIC HOSPITAL, DUBLIN.

## AMAUROSIS AFTER ERYSIPELAS OF THE FACE.

(Under the care of Mr. STORY.)

[Reported by Mr. A. H. BENSON, Assistant-Surgeon.]

THIS case is interesting taken in connection with the somewhat similar cases reported by Dr. Hermann Pagenstecher, and Mr. Jonathan Hutchinson, in the *Royal London Ophthalmic Hospital Reports* for February 1871.

John Duke, aged 41, shoemaker, was never a smoker, but was always a "heavy drinker" until July last, when he suffered from stoppage of his urine. He had had perfect sight in both eyes until a few weeks ago. On Christmas night, he fell and cut his lip. Three days afterwards, he got a shivering, and then the right side of his face became swollen, red, and painful. His right eye, which then had perfect sight, closed up entirely, and remained so for a month; when, on opening it, he found it to be totally blind. The doctor, under whose care he was, told him he had erysipelas. On entering the hospital, the red blush was still over the cheek and eyelids. There was also a peculiar xanthelasmic-looking eruption on both upper and lower lids, which soon became elevated, and exuded a thin unhealthy pus. After some days, it acquired a dry warty appearance. The conjunctiva was inflamed and thickened, but the cornea was clear. The pupil was large and insensible to light, but dilated fairly under atropia. The whole appearance of the eye was remarkably dull and glazy. There was considerable paresis of the levator palpebræ superioris, and limited action of all the ocular muscles ( $T + 1, V = 0$ ). In the left eye, the sight was perfectly good, and the refraction emmetropic. In the right eye, the dioptric media were all somewhat hazy. Three small pigmentary specks were visible on the anterior surface of the lens, and some stellate opacities in its substance. The disc was very pale, and had a bluish atrophic appearance, especially at the outer side. The arteries were extremely small, and very many of those running downwards were entirely empty, appearing as white lines, without any central streak of red. Some of the arteries contained blood for a short distance from the disc, others were bloodless throughout. There were a number of dark broad lines radiating from the disc, which were taken to represent veins in which the blood had stagnated. Their margins were rather ill defined, owing to the haziness of the media; but, from their disposition, and the relations they bore to the disc and arteries, there seemed little doubt that they were occluded veins. In some places, the white lines of the empty arteries could be traced over these broader dark lines. There were collections of pigment and possibly some blood effusions in the region of the yellow spot. The heart and urine were not examined. Further observation of the case was prevented, as, owing to the limited accommodation, the patient could not be kept in hospital.

## CONGENITAL MALFORMATION OF THE HAND.

THE following malformation of the hand of a girl aged 13 was noticed in the out-patient department of the hospital. The right arm was slight, but shapely. The carpal articulations appeared perfect; but the metacarpal bones were only two in number, apparently those of the thumb and little finger. These, though in contact at their carpal extremities, diverged as in the normal hand, so as to be separated, at their phalangeal extremities, by about an inch of soft muscular tissue. The metacarpo-phalangeal articulations were freely movable, but, between the first and second phalanges, the movements were very slight; these phalanges being united at their peripheral extremities. The third phalanx was single, composed of the conjoined phalanges, and was set at right angles to the second. It supported a single enormous nail, three-quarters of an inch wide and half-an-inch deep. The whole hand thus appeared rhomboidal in shape, with a crook at right angles to its extremity. This crook was of immense prehensile utility; with it she could hold a pencil, lift a book, etc. Her mother, who had a number of other children, all free from deformity, blamed a severe squeeze of the hand which she got from a drunken man, who hurt and frightened her, when three months gravid. The case is interesting as adding another to the list of congenital malformations, apparently the result of maternal impressions.

## MATER MISERICORDIE HOSPITAL, DUBLIN.

## OPERATION FOR FEMORAL HERNIA: MIXED NARCOSIS.

(Under the care of Mr. COPPINGER.)

R. D. K., A WOMAN aged 72, was admitted on February 7th, suffering from strangulated femoral hernia. The hernial tumour had become irreducible four days before the patient's admission, and was hard and

very tender on pressure, while the characteristic abdominal pain and vomiting were present in a severe degree, and had existed, according to the patient's account, for three days. An operation was determined on at once, and was performed after the antiseptic method, and under a carbolic spray, maintained by one of Mr. Fletcher's foot-bellows. The sac was opened and found to contain a large quantity of omentum with a small knuckle of intestine. The latter was easily reduced, and the entire of the omentum returned, with the exception of a small portion adherent near the neck of the sac.

The patient made a good recovery, a portion of the adherent omentum sloughing away, and the remainder acting as an efficient plug in occluding the abdominal aperture.

REMARKS.—Although ether has been used in this institution almost exclusively as an anæsthetic for the last four years, it was not considered suitable in this case, on account of the emphysematous condition of the old patient's lungs, and the presence of some bronchitis. On the other hand, the method of "mixed narcosis" seemed to offer peculiar advantages, and was accordingly adopted and carried out in the following way.

A third of a grain of morphia in solution was introduced under the skin, and methylene bichloride then administered by means of a folded towel. The operation, etc., occupied nearly three-quarters of an hour, and during that time the patient remained apparently in a deep sleep, but without the evidences of heart-depression, in pulse or aspect, which are frequently present in cases in which chloroform or methylene is administered alone.

The antiseptic method in its entirety was adopted in this case, although it is not very popular in this hospital, on account of the large amount of space allotted to each patient, and the comparative youth and aseptic condition of the building.

The recovery, at such an advanced age, of so grave a case, was unusual, and was probably to some extent due to the effect of the elastic omentum, which partially filled the neck of the sac at the seat of the stricture, in preventing the nipping and destruction of the intestine.

## ROYAL INFIRMARY, EDINBURGH.

### COMPOUND COMMINUTED FRACTURE OF LEG.

(Under the care of Mr. SPENCE.)

FOR the following report we are indebted to T. F. Chavasse, M.B.

W. R., aged 40, railway carter, was admitted May 5th, 1877, having been kicked half an hour previously by a heavy draught horse.

On admission, the patient was slightly intoxicated. An examination revealed a compound comminuted fracture of the right leg, both bones being broken at their middle thirds; the wound communicating with the ends of the bones was situated over the interosseous space, and was large enough to admit the end of the little finger. No pulsation could be felt either in the anterior tibial or dorsalis pedis arteries. About three ounces of carbolic lotion (1 to 20) were used for washing out the wound, care being taken that all the injected fluid escaped; a pad of lint steeped in the same lotion was then applied, and a suitable splint adjusted to the limb. The case progressed satisfactorily for thirty-six hours, when, without any noticeable premonitory symptoms, the patient was found to be breathing stertorously and quite unconscious. The right buccinator muscle was weaker in its action than its fellow. The pupils were dilated, but contracting under the influence of light. The breath was somewhat fetid. He had heavy sweating. Temperature, 101.2; pulse, 100; respirations, 20. Examination of the chest revealed nothing abnormal. The urine that was drawn off contained no albumen and did not answer to the perchloride of iron test for carbolic acid. The patient remained in the same condition until May 12th, when he died. Life was maintained by means of nutrient enemata and occasionally feeding with a stomach tube. The temperature of the body averaged 101 deg. Fahr.; but six hours before death rose to 105 deg. Fahr. The wound in the leg remained perfectly healthy until the last day of life, when a slight fetid odour emanated from it; this, no doubt, was due to the low state of vitality generally.

POST MORTEM EXAMINATION.—This was made by Dr. Wyllie, Pathologist to the Infirmary. There was no trace of injury of the head. The brain was slightly congested, but the substance of the organ was otherwise healthy. There was a small amount of subarachnoid serous effusion, and the lateral ventricles contained each about three ounces of fluid. The vessels of the brain were normal, and there was no sign of embolon or thrombus. The spinal cord was slightly congested. The lungs were both much congested, the inferior lobes in both showing the commencement of a low form of pneumonia. The so-called

"fatty" embolon was carefully sought for, microscopically and otherwise, but with a negative result. The heart weighed twelve ounces, and contained an *ante mortem* clot in the right ventricle, extending up the pulmonary artery to a point just beyond its primary division. All the vessels of the affected limb were examined, but nothing was found. The spleen was very pulpy; the liver and kidneys were somewhat congested. There was no pus in any of the large joints.

REMARKS.—The case is one of interest from the fact that certain well marked symptoms, present during life for a period of six days, could be assigned to no cause after a carefully made and prolonged *post mortem* examination had been made. The diagnosis of "fatty embolon" was not borne out; although, from the patient having a fracture with the medullary cavities widely opened into, this seemed probable. In the well established cases that have succumbed in consequence of fatty embolon, the majority of those reported by Busch, Wagner, and other German authorities were the result of fractured bones; but Dr. Hamilton lately showed, at a meeting of the Medico-Chirurgical Society of Edinburgh, some microscopical specimens of this form of embolon, which had been taken from the pulmonary artery of a boy who had died comatose some hours after his liver, which was of a fatty nature, had been accidentally ruptured. Whether the injection of a solution of carbolic acid in cases of compound fractures hasten or retards the formation of a fatty embolon, is at present a matter for consideration; but at all events, care should be taken that the fluid injected into wounds of this nature should have a ready way of escape; or a complication, in the shape of carbolic acid poisoning, may arise.

## SELECTIONS FROM JOURNALS.

### THERAPEUTICS.

CARBOLATED CAMPHOR IN DIPHTHERIA.—M. Soulez employs carbolated camphor in the treatment of diphtheria; the false membrane seems to lose its inherent vitality, and no inflammatory effects follow. M. Soulez dissolves camphor in crystallised carbolic acid, which has itself been dissolved in a very small quantity of alcohol—nine *grammes* of carbolic acid to one *gramme* of alcohol. He uses it either alone, or mixed with an equal weight of oil of sweet almonds.

SUBCUTANEOUS INJECTION OF CHLOROFORM.—M. Ernest Besnier has used subcutaneous injections of chloroform, not only in cases of neuralgia, but in all varieties of pain. M. Besnier performs the injection in two stages, introducing the needle first, and then adjusting the syringe so as to be sure not to penetrate the vein. The injection should be made in the subcutaneous cellular tissue, so as to avoid local phlegmasia or persistent pain at the seat of the puncture. In reference to this practice, M. Hardy calls attention to the fact that chloroform soon becomes acid.

CITRATE AND BROMHYDRATE OF CAFFEINE.—At a recent meeting of the Société de Thérapie in Paris, M. Gubler pointed out the diuretic properties of citrate and bromhydrate of caffeine, in doses of fifty *centigrammes* (seven grains and a half), in the form of hypodermic injection. The diuretic effect is almost immediately produced, whilst with digitalis it is delayed for two or three days. Caffeine may be given as a draught for the same purpose, in doses of thirty *centigrammes* (four grains and a half). Caffeine increases the vascular tension less than digitalis does. The maximum action of digitalis is reached on the fourth or fifth day; and, if the administration of digitalis be prolonged, an accumulation of action is produced—that is to say, an opposite result to that desired. M. Gubler generally prescribes the alcoholic tincture, in doses of twenty drops. If the kidneys do not yield to the action of this remedy, M. Gubler pronounces them to be incapacitated for use.

### SURGERY.

FATAL PISTOL-SHOT WITHOUT PERFORATION OF THE SKIN.—Dr. Hofmann (*Lehrbuch der Gerichtl. Medicin*, 2 Band, Wien, 1878) relates the following remarkable case. A man, aged 40, fired a pistol-shot at himself in the region of the left breast. A skin-burn resulted of the size of the palm of the hand, but no rupture of continuity of the external skin. Beneath this, there was an effusion of blood; the costal cartilage was broken. In the pericardium lay a pound and a half of blood; and at the apex of the heart, on each side of the longitudinal sulcus, was a rent of the muscular fibres, extending into the cavities of the ventricles.

## REVIEWS AND NOTICES.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1876, vol. xviii. London: Harrison and Sons. 1877.

THE eighteenth volume of the Statistical, Sanitary, and Medical Reports of the Army Medical Department have just been presented to Parliament. The various dates connected with this Blue Book are at first somewhat puzzling to the general reader. The contents principally refer to the health of the army during the year 1876; the introductory letter from the Director-General to the Secretary of State for War is dated November 1877; and the volume is only issued in February 1878, although it would appear from the title-page and cover that it was "presented to both Houses of Parliament by command of Her Majesty" in 1877. It may be readily understood that the mass of figures obtained from the many distant parts of the world comprehended in the report cannot be examined and tabulated, until some months have lapsed after the close of the year to which the figures refer; but the discrepancy between the apparent date of presentation to Parliament and that of issue is not so easily explained.

The contents of the present volume correspond in arrangement with those of the two preceding volumes. Statistical tables summarising the general state of health and the results of sickness among the whole of the white troops of the British army, whether serving at home or abroad, during the year 1876, are first given. We have then statistical reports on the health of the troops serving in the various military districts of the United Kingdom. Similar statistics follow respecting the troops serving in the Mediterranean, Canada, Bermuda, the West Indies, Western Africa, the Cape of Good Hope, Mauritius, Ceylon, China and the Straits Settlements, the Fiji Islands, and, lastly, in the three great Presidencies of India. A mere enumeration of the names of these stations, widely distributed as they are over the face of the globe, calls the attention very forcibly to the variety of physical conditions under which British soldiers have to serve. To complete the survey of the health of the army, it is necessary that the sickness and mortality among the troops proceeding on foreign service, returning to England, or passing from one station to another by sea, should also be taken into account. A separate section is, therefore, devoted to the health of troops on board-ship. The medical and sanitary reports received from the various stations where the troops have been quartered are printed immediately after the statistical details relating to them, and often serve to explain the figures in the tables. This is a more convenient and useful arrangement than the plan which was adopted in some former volumes, in which the statistical, medical, and sanitary reports were shown separately. An appendix, consisting of a series of reports by medical officers on various special subjects, closes the volume.

The average strength of the army serving in all parts in the year 1876—that is, of non-commissioned officers and privates (the number of commissioned officers is not shown)—is stated to have been 169,197. These figures are limited to white troops, and do not include the men of certain special corps, like the Malta Fencibles, which are recruited at foreign stations. But, after all, how small the number appears, if they be compared with the numbers on the rolls of the armies of the other powers of Europe, especially when it is remembered that the troops of these powers habitually serve almost exclusively in the countries to which they belong, while those of Great Britain are detached and scattered over all parts of the world! The number of admissions into hospital during the year was nearly equal to the total number of men above mentioned; viz., 166,319, or 983.0 per thousand; the number of deaths resulting from these admissions was 1,921, or 11.03 per thousand; while 3,769, or 21.63 per thousand, were discharged from the service as invalids. The mortality from sickness and injury bears a favourable comparison with that in the previous year 1875, during which, the total strength of the troops being almost exactly the same, the deaths amounted to 2,169, or 12.47 per thousand. But even this death-rate was a very favourable one, when compared with the ratios of most other European armies; armies, too, free from the risks of tropical service to which a large portion of the British army is constantly exposed. The fact that the death-rate among the soldiers of the British army has now been reduced to a small fraction over one in a hundred *per annum*, the men in all climates in which our troops are quartered being included in the estimate, and all causes of death, whether from disease, injury, or accident, being taken into account, is one well worthy of attention. It is all the more so when

it is remembered that close upon sixty thousand of the soldiers included in these statistics were serving during the year in a part of the world which, within the memory of many persons, was dreaded on account of its unhealthy attributes; viz., India. The reduction in the general death-rate certainly points to a meritorious discharge of the duties which devolve on the medical department of the army; for, unless the specific influences of the different regions in which the troops have been placed had been carefully studied, and the conditions necessary for the preservation of health under them well considered, the amount of mortality must have been much larger than that which has just been mentioned. There is reason for hoping that a further reduction in the death-rate may be shown in future reports. Many sanitary recommendations appear in the medical reports forwarded from foreign stations and are quoted in this Blue Book; and, as the difficulties in the way of carrying them into execution, on account of expense, or from other impediments, are gradually overcome, the sickness and mortality among the troops must proportionally, at the same time, be lessened.

Some curious facts are brought to notice when the amount of sickness and mortality in particular stations is examined. As a station, that of the West Indies has always been regarded as one to be avoided, on account of its deleterious climate. Taking the ten years preceding 1876, the year embraced by the present report, the average annual death-rate among the white troops quartered there was 16.47 per thousand of the mean strength. But, in the year 1876, the death-rate was only 3.68 per thousand: lower than it was in any other station, and far lower than it was among the troops quartered at home in the United Kingdom. It is true the number of troops now stationed in the West Indies is small, the average for the year amounting only to 1,086 men; but the slight amount of fatal illness among them is, nevertheless, a remarkable fact. The ratio of mortality among the black troops in the West Indies was far higher; viz., 18.62 per thousand. There has not been any very marked reduction, either in the amount of sickness or the proportion of deaths, as compared with previous years, among the troops quartered in the United Kingdom. Contrasting, as before, the ten years preceding 1876, the average annual number of admissions into hospital during this period was 823.0 for every thousand men, and the proportion of deaths among them 9.11 per thousand. During the year 1876, the corresponding numbers were 813.7 per thousand and 8.43 per thousand. A more favourable reduction, particularly as regards rate of mortality, is shown among the large body of troops quartered in our Indian possessions. The number of admissions into hospitals in India during the ten years preceding 1876 was, on the average, 1,421.7 annually for every thousand men in the country; the yearly number of deaths during the same period was at the rate of 22.45 per thousand. During 1876, the hospital admissions were reduced to 1,330.1 per thousand and the death-rate to 16.10 per thousand. By far the highest mortality-rate during 1876 occurred among the small party of Royal Engineers at Levuka, in the Fiji Islands, a station occupied for the first time by British troops in September 1875. Among the fifty-seven non-commissioned officers and men comprising the force, there were three deaths; the ratio being, therefore, 52.63 per thousand. Two of the deaths were caused by heat-apoplexy, while the third seems to have been as much due to excessive drinking as to solar exposure. The medical officer in charge mentions that the drink used by the men in this command is of a very deleterious kind. Whether the Fiji Islands, when better known, will be found to have any local sources of unhealthiness other than those which are common to all hot countries, remains to be seen; experience, so far as it has gone, does not point to any.

It would occupy too much space, were the facts brought out by the statistics before us in regard to each of the particular stations in which the troops were quartered, given in detail. But, as the subject of the relative prevalence of venereal disease among soldiers in the United Kingdom, in stations under the Contagious Diseases Acts, and of it among those in stations not under the Act, is one which has excited much controversy, it may be useful to quote the information which the statistics in the present report afford in this respect. The average annual strength of troops, and the number of admissions for primary venereal sores, at fourteen of the principal stations in Great Britain which are placed under the Act, are shown in a tabular form; and, in another table, the strength and number of admissions at fourteen large stations which are not under the Act. A comparison of these two tables shows that the ratio per thousand of hospital admissions for primary venereal sores was thirty-three in the stations under the Act, while the corresponding proportion in the stations not under the Act was eighty-two per thousand. The group of fourteen stations under the Act shows a reduction of two per thousand in 1876 as compared with 1875; the contrasted group of stations not under the Act

shows an increase of three per thousand in 1876 as compared with the previous year. The highest ratio of admissions for primary venereal sores in the stations under the Act during 1876 was in the camp at Aldershot; viz., forty-seven per thousand; the lowest in the Curragh camp, in Ireland; viz., eighteen per thousand. The highest ratio of admissions among the stations not under the Act occurred in London; viz., one hundred and forty-six per thousand; the lowest, among the few men stationed at Athlone, in Ireland; viz., eight per thousand. The ratios were very high at Sheffield and Manchester; viz., one hundred and nineteen and one hundred and thirteen per thousand respectively. If, instead of taking the admissions among the troops in the twenty-eight large stations included in the two tables just mentioned, the fourteen stations under the Contagious Diseases Act are placed in one group, and all other stations at which troops are quartered are contrasted with them, then the following results are obtained. The admissions for primary venereal sores among the 48,620 men quartered in the stations under the Act were 1,622, or, as before mentioned, thirty-three per thousand; the admissions among the 38,073 men at all other stations were 2,416, or sixty-three per thousand. We advisedly restrict ourselves to a bare enumeration of the facts as shown by the figures in the statistical returns before us.

The chief articles in the appendix are a "Report on the Progress of Hygiene for the year 1876 and part of 1877", by Dr. De Chaumont of Netley, on the same plan as the annual reviews of the same branch of science published by the late Dr. Parkes, F.R.S.; a "List of the Surgical Operations performed at the Royal Victoria Hospital, Netley, during 1876, with abstracts of the more important cases", by Surgeon-Major Porter, Assistant-Professor of Military Surgery; "A Contribution to the Etiology of Heart-Disease in the Army", by Surgeon Davy, A.M.D.; "Remarks on the Normal Temperature of the Body in the Tropics", by Surgeon-Major J. Johnston, M.D.; "The Medical History of the Laroot Field Force", by Surgeon-Major G. S. Davie; and a "Report on the March from Bhamo, in Upper Burmah, to Manywe, in Yunnan" (the scene of the murder of Lieutenant Margary, which attracted so much notice in the English press about two years ago), by Surgeon W. J. Charlton, A.M.D. These articles well deserve special remark, and we regret that the space at our disposal does not admit of their being more particularly referred to in the present review of the volume before us.

A notice appears at the end of the appendix that the next subject for the Alexander Gold Medal and Memorial Prize of £50 is "the influence of drinking-water in originating or propagating enteric fever, diarrhoea, dysentery, and cholera; to be illustrated, as far as possible, by instances which have come under the personal observation of the author of the essay".

LEÇONS SUR LES MALADIES DU FOIE, DES VOIES BILIAIRES, ET DES REINS. Par J. M. CHARCOT. Paris. 1877.

THIS is a reprint of lectures which have appeared in the pages of the *Progrès Médical*, and represents courses delivered by M. CHARCOT at the Collège de France. Nowhere can we find a more complete account of certain parts of the pathology of the liver and kidneys. Few lecturers are at such pains to make all they teach so clear, still fewer possess that remarkable versatility which enables M. Charcot to engage in many different lines of research with so much enthusiasm and so much skill. The arrangement of the matter is excellent; and the care with which the normal condition of the organs is displayed previously to considering the pathological deviations, shows how thoroughly M. Charcot is in earnest in his teaching. The book contains many woodcuts and some chromo-lithographs, which add still more to its value.

The first six lectures are taken up by a consideration of the normal histology of the elements of the liver, and the pathological changes to which they are liable. Lectures 7, 8, 9, 10, and 11 are devoted to the Physiology of the Liver in its several functions of bile-making, glycogenesis, and oxidation of protein. The next six discuss Biliary Calculi, their origin, nature, and the results of their presence in the bile-passages. M. Charcot regards the intermittent fever of biliary lithiasis as the result of the formation of some morbid poison in the pent-up bile.

The most original part of the book is the account of the various forms of cirrhosis. As our readers know, M. Charcot, in conjunction with M. Gombault, has made a large number of experiments upon guinea-pigs by ligaturing the ductus communis choledochus, the results of which, together with MM. Charcot and Gombault's views of their bearing upon the pathology of cirrhosis, were published in the *Archives de Physiologie* for 1876. These were in support of the thesis of M. Hanot, now well known, in which he maintains that there is a form of cirrhosis clinically and anatomically distinct from the common cirrhosis or hob-nailed liver, differing by the early appearance and persist-

ence of jaundice, by the absence of ascites, and by the enlargement of the liver. Under the microscope, this form of cirrhosis presents a remarkable development of the biliary canaliculi in the portal canals and interlobular spaces and fissures, which are at the same time much enlarged from the growth of fibrous tissue. These numerous canaliculi he considered to be the result of a catarrhal inflammation of the larger ducts, which, by obstructing the outflow of bile, leads to dilatation and inflammation of these capillary ducts, which finally become lined with epithelium. MM. Charcot and Gombault found these conditions repeat themselves in the animals whose bile-ducts they had ligatured; and MM. Kelsch and Kiener shortly afterwards, in a contribution to the same journal, threw fresh light upon the circumstances under which these new canaliculi are formed. According to them, a hepatic trabecula transforms itself by hypertrophy into a gland-tubule, by atrophy into a bile-duct; and they draw attention to the fact, already signalled by Hanot and Charcot, that the tendency of the new material in hypertrophic cirrhosis is to invade the acini and surround single trabeculae, thus explaining the greater frequency of these appearances in this form of cirrhosis. From this tendency of the new growth to invade the acini, M. Charcot proposes to call it monolobular or intralobular, while the ordinary form he would call perilobular or interlobular. M. Charcot also believes that the new growth can be seen to start from around the bile-ducts, and he regards the starting-point of the affection as a catarrhal inflammation of the smaller bile-ducts leading to retention of bile, in which changes take place giving rise to irritating products with inflammatory results. This interesting subject is still *sub judice*; the microscopical details of the cases reported by Hayem (*Archives de Physiologie*, 1874) do not support the view that these are constant appearances, and our own experience does not incline us to accept these new views as quite proved at present.

The second part of the book gives a sufficiently clear account of the forms of Kidney-disease, usually classed by us as Bright's disease. The account of the morbid anatomy of granular kidney is remarkable for its omission of all but the slightest reference to the state of the small blood-vessels in the kidney, and of all to those of the pia mater, etc. M. Charcot also makes the mistake of asserting that the blood-vessels of the kidney have their lumina diminished, although, as has been proved by Thoma, this is altogether exceptional. In discussing the polyuria, M. Charcot seems unable to regard any of the current views as to its cause very sufficient; he does not appear to recognise that hypertrophy of the heart takes place in parenchymatous nephritis also. In speaking of dropsy, M. Charcot falls into the common error of ascribing it to the loss of albumen alone, instead of, as Bartels has so well shown, connecting it with the accumulation of water in the blood from the interference with the renal function.

We warmly commend the book to the profession; it is one more obligation which M. Charcot has laid upon it.

## REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

### A NEW EAR-SPECULUM.

IT would seem, considering the many eminent authorities who have given attention to the construction of ear-specula, to be impossible to make any addition to the ones required for ordinary purposes that could be considered as an undoubted improvement; and yet I am quite sure that the beak-shaped speculum, which has been constructed for me by Messrs. Stevens of Gower Street, possesses this manifest advantage, that it can be easily and effectually cleansed of cerumen or offensive discharges after each time of using: an advantage in which the Wilde's and Politzer's ear-specula are deficient. It is simply an ordinary Toynbee's speculum furnished with a door opening upon a hinge placed upon the side of the instrument half an inch from the broad end; this door being made to accurately fit the remaining portion of the speculum. The door, when the instrument is in use, is steadied by the pressure against the wall of the meatus; whilst it enables us, if we wish, to slightly dilate the speculum when introducing a plug of cotton-wool. Lastly, it possesses an advantage over that introduced by (I think) Mr. Laidlaw Purves, and which, consisting of two equal portions, is dilatable by springs at their broad end, that there are no springs to break, or mechanism that is at all likely to be disarranged; and its cost is but very little more than that of an ordinary Toynbee's speculum.

ROBERT T. COOPER, M.D.

## BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 16TH, 1878.

### THE VITAL AND PHYSICAL ASPECTS OF VENTILATION.

THE subject of ventilation, its importance, the consequences of an imperfect supply of air either in quantity or in quality, are just beginning to dawn distinctly on the public mind. The erection of the new Law Courts gives a peculiar point to the subject at this moment; for, we may remark, the errors of ventilation, or rather of the want of it, seem to attain their highest perfection in the present arrangements of our courts of justice. How an educated body of men like judges and barristers can tolerate the existing state of affairs, is simply a matter of wonderment to those interested in hygiene; and it only becomes comprehensible on the hypothesis of the deep-seated conservatism which is attached to the law, and the respect manifested for what has existed in the past merely because it has been. Lawyers have an affectionate veneration for precedents, which apparently extends even to a regard for imperfect ventilating arrangements. The growing acquaintance with the fact that we require so much oxygen *per diem*, and therefore must have so many cubic feet of air from which we may obtain it, one would have thought might have reached the judicial bench, if stern facts did not contradict this supposition. Is it not on record that an eminent judge has ordered all the windows of his court to be closed, because he was cold, and thus business had to be conducted by persons in a state of partial carbonic acid poisoning? Why it is that an elderly judge comes to complain of loss of body-temperature when the juniors are warm will be apparent shortly, and a very significant fact it will be found.

Before proceeding to consider the physical aspects of ventilation, it may be well to review some of the consequences of an imperfect supply of oxygen to the body. This will give weight to considerations as to the practical attainment of proper ventilation. We may commence by saying that a proper and sufficient supply of oxygen is a most important matter for the removal of waste materials from the body. In the first place, waste and effete tissues are removed by oxidation, and, if not properly oxidised, remain in the system and work mischief there. Uric acid, which is really "gout-poison", is a waste form of nitrogenised material, which, if further oxidised, would be converted into the more soluble urea, and thus find its way out of the body by the watery excretion through the kidney. The irascibility and irritability which are the consequence of the disturbance of the cerebral cells created by blood supercharged with "gout-poison" are not only unpleasant to the individual himself, but are eminently calculated to make it unpleasant for those around him; and such physio-psychological conditions are not favourable to mental calm and the administration of impartial justice. The late Dr. Bence Jones denominated Bright's disease a disease of "suboxidation"; that is, it is, from one point of view, a disease whose ulterior consequences are linked with a defective oxidation of the waste material of the body.

Then there is the function of the liver. All those who have read Dr. Murchison's admirable lectures on *Functional Disturbances of the Liver*, are impressed with what he says about the function of the liver in breaking down and oxidising the albuminous matters which are not required for tissue-repair. The liver is the furnace in which effe-

tissue-material, old red blood-corpuscles, and the surplussage of albuminoid food, are all burnt off by a process of oxidation. Biliousness is that condition which arises when the oxidation is imperfect, when, indeed, the waste material is in excess of the oxidising powers. It may arise either from too great indulgence in food beyond the functional powers of an active liver; or it may arise where a functionally feeble liver cannot cope successfully with an ordinary amount of food. The consequences are that the blood is loaded with waste material, the imperfectly oxidised products of nitrogenised material, as bile-acids or uric acid. Headache, irritability, and depression are the results of blood charged with bile-acids; and it seems not improbable that some of those acrimonious disputes which we see recorded in the newspapers as having occurred in this or that law-court, may take their origin in the action of bile-acids upon the brain-cells of the contentents. All people are not fortunate enough to have active capable livers equal to their work under unfavourable circumstances; and, therefore, a free supply of oxygen is very desirable, to enable a feeble liver to proceed with its work of oxidation. A great deal of the biliousness and gout which come before the profession is due to the conditions under which such patients live; as the barrister in an insufficiently ventilated law-court, the merchant in a stifling den in the midst of his warehouse—and who that has visited a business man in his close chamber, or still worse, the glass box in which many spend hours with the accounts and the ledger, does not carry away with him a strong remembrance of the atmosphere, and of the relief felt on returning to the by no means too pure air of the sale-room? Many hours a day so spent, to be followed by a late dinner, for a great portion of the year by artificial light, and then the social requirements of a family, necessitating the staying at home and living amidst further artificial light and warmth, give the liver of the British paterfamilias little chance of fairly oxidising his spare and waste matters; while the billiard and the smoking rooms of most houses and clubs are exercising the same pernicious influences over the younger tissues of his sons. It is needless to say that the overheated rooms in which ladies spend their days at present are not beneficial to their oxidising processes. A fall of temperature, with the increased oxidation so brought about, is neutralised by free resort to artificial heat, and thus a summer temperature is always maintained. The profession is indebted to imperfect oxidation for a great deal of its most lucrative practice.

There is another consequence of suboxidation which is most grave, and that is the imperfect removal of waste tissue. When a tissue has become effete and worn out, it is removed by a process of oxidation, and new material laid down in its place. The removal of the old material is essentially necessary, and must precede the formation of new tissue in its place. The blood may be highly charged with the material for tissue-repair, but this all goes for nothing if the old effete matter be not first removed. Fatty degeneration of the heart goes on with a sufficient supply of proper and suitable food, because the fatty debris of the wearing out muscular tissue is not removed. Indeed, the richer the food and the more liberal the supply of it, the more the respired oxygen is taken up by the food and the less is left for the removal of decaying tissue. The conditions under which geese are placed in order to procure that large and fatty liver which furnishes the delicious *foie gras* are those of liberal supplies of food—indeed, by cramming the poor creatures when their appetite is sated, and by keeping them at an unnaturally high temperature around a fire. The feeder has found that, by an excess of food and a high surrounding temperature, those fatty and degenerative changes he seeks are most readily and certainly secured. This is a grim fact when seen in relation to the production of fatty degeneration in the tissues of man. Exactly the same process goes on where man is so placed as to take food in excess of the positive needs of the organism, and oxidation is insufficient. Even if the dietary be a restricted one, still a sufficiently defective oxidation will attain the same results. This is a very important matter for elderly persons. Dr. Michael Foster, in his well-known *Text-Book of Physiology*, makes this weighty statement: in speak-

ing of old age and its liability to calcareous and fatty degeneration. "Everywhere we see a disposition on the part of protoplasm to fall back upon the easier task of forming fat, rather than to carry on the more arduous duty of manufacturing new material like itself. Everywhere almost we see a tendency to the replacement of a structural matrix by a deposit of amorphous material." Thus we see that it is not merely the development of fat in and around the muscular fibrillæ—the conversion of an ordinary connective tissue-cell into a fat-cell; it is the structural decay of the muscular bundles themselves which is to be feared as life advances. The natural tendency to such degenerative change is fostered by a liberal dietary, a high temperature, and an imperfect supply of oxygen. It has been stated that a number of judges have died of fatty degeneration of the heart. One died instantly, while delivering his charge; and such a fact is readily comprehensible. It was stated last week that elderly judges like to be kept warm, and that they have been known to order every window of a court to be shut when other people felt suffocating for want of air; and that they require a higher temperature than the younger men around them. Now, why is this? It is due to the fact that the imperfect combustion going on within the older men is insufficient to maintain the normal body-temperature except under very favouring circumstances, and that they are thus susceptible to thermal changes. But this means that they are in a condition of suboxidation, with all the consequences thereof. In fact, they differ from the Strasburg goose but in degree; they are unwittingly placing themselves under those very conditions which have been found most favourable to the development of a fatty degenerative change. If the oxidation going on within them were as active and as complete as that of younger men, they would not require this high surrounding temperature; but their heat-production is small, and thus they chill under a temperature which other persons feel oppressive. In fact, for them and their tissue-needs, a more liberal supply of oxygen is desirable than is required for younger persons; but, instead of that, they insist upon a high surrounding temperature, involving an imperfect supply of the oxygen-bearing air, because their heat-production is defective. These old men have got into a vicious circle, which is only broken by death, sooner or later.

In addition to these grave consequences of imperfect oxidation, the question of "catching cold" is intimately linked with that of ventilation. Changes in the vascularity of the lining membrane of the air-passages are the means by which cold air is warmed before it reaches the ultimate air-vesicles, and disturbances in this lining membrane furnish the frequent condition of catarrh. The catarrh may be nasal or it may be bronchial; but the exciting cause is a disturbance in the vascularity of the respiratory tract. In full health and under ordinary circumstances, these changes of vascularity are brought about according to circumstances, and give no evidence of disturbance. At other times, the accommodation is not achieved without some remaining disturbance. Long continuance in a warm surrounding atmosphere produces a sort of paralysis of the vaso-motor fibres of the vessels of the lining membrane of the air-tubes; and then, when the individual emerges into the cool, or may be cold, air outside, these vessels dilate in a paralytic manner, and, this condition continuing, a catarrhal state is set up and is slowly recovered from as these blood-vessels regain their tone. Consequently, those who have spent hours in a stifling court, at a high temperature, are specially liable to suffer from catarrhs so produced. When, in addition to this local condition, there is a general loss of heat by the cutaneous vessels being also paralytically dilated, then a "cold" is felt and a febrile condition set up until the thermal equilibrium is restored. We know, however, that a cold may exist without a catarrh, and that a catarrh may be independent of a cold. It is not merely these thermal influences which are involved in the subject of efficient ventilation, but there is the further question of the effects of what the air may contain and carry with it. In a work on asthma by Dr. Berkart, who has kindly afforded us an opportunity of seeing his proof-sheets, the effects of mechanical irritants and che-

mically acting agents, as irritating gases, are considered at some length. This writer holds that these causes of disturbance in the vascular lining membrane of the air-tubes are not sufficiently appreciated; and that often they are in action when thermal influences are credited with the production of the morbid conditions induced. Be that as it may, such irritants of the air-tubes are truly potent for evil, and have a malign influence on delicate lungs and air-tubes. Especially is this the case when gas has to be burnt in the daytime, not for illuminating purposes, but in order to warm a badly heated court-house. It is certainly surprising that barristers should not be more careful of themselves, and much of the disease to which these persons are subject is not due to overwork and worry, but to bad hygienic arrangements which might be remedied.

Judges and Queen's Counsellors are elaborate productions, we are inclined to hold. Their brains must be of good quality, to begin with, and be very carefully cultivated before their owners attain their distinguished positions. Consequently, they ought to be worthy of every care that can be taken of them, and, amongst the rest, they ought to have their court-rooms properly as well as efficiently ventilated. What the arrangements made for the new Law Courts are, we do not know; but we know very decidedly what they ought to be. They should resemble, as closely as circumstances will permit, those of our Houses of Parliament, which leave little or nothing to be required. Where the national legislation is conducted, a system of ventilation is in action which is admirable; but how far provision of a like character is made for conduction of private litigation, we cannot say. If the arrangements of the Houses of Parliament are adopted, there will be no ground for complaint. These arrangements provide for all possible contingencies and emergencies. The air is taken from the quiet court-yards of the Houses; it is dried and warmed in cold weather by being passed over a large number of metal plates, which are not too highly heated, in order to avoid the fierceness of superheated air. In hot weather, it is cooled and washed by being subjected to a large number of minute sprays of water and driven over blocks of ice. In fogs, it is driven through layers of cotton-wool, which soon become black and foul by the multitudes of soot-particles, etc., arrested by them; so that repeated renewal is necessary. Machinery exists by which air can be driven in according to the requirements of those inside, and then the used air escapes by numerous orifices in the ceiling into tubes connected with a general exhaust-current in the lofty clock-tower, where there is a long chimney with a fire at its base. In order to prevent the air from becoming too dry, wet and dry bulb-thermometers are fixed up; and, if a difference of seven degrees exist betwixt them, then the air is moistened. The air of the House is changed six times every hour, if required, and, of course, this largely depends upon the number of members present and the amount of gas which is burnt. If there be a full house, the demand for air is large; when empty, the amount of air driven in is small, and according to the number in the house and temperature outside, so the air may require neither heating nor cooling. A vigilant watch is kept as to the filling and emptying of the house, and an ingenious mechanical application at the orifice where the air enters prevents the sudden draught which would otherwise be induced by the incoming or outgoing of a number of members at once. Such arrangements might be adapted to our Law Courts; but there is one difficulty to be encountered, and it is this. It will be impossible to provide in the Law Courts the large cubic space of air which the great size of the Commons' House permits to each member. Then comes the question of the renewal of the air so many times per hour; for the smaller the cubic space, so much oftener must the air be changed to secure the requisite number of cubic feet per hour. This is a great practical difficulty; for, if the air of an apartment be changed more than four times per hour, it is apt to be disagreeably chilly, except in warm weather. Consequently, some method of warming the incoming air should be adopted; for elderly judges, with a low body temperature, cannot tolerate currents of unwarmed air coming in by open windows

Neither should they be so exposed. Warmed air in a full sufficiency for their tissue-needs and proper oxidation should be furnished to them. By such means, they would be less injured than where they have to secure artificial heat at the expense of an insufficient supply of oxygen; and so, indeed, to cause further need for a high surrounding temperature, because of their own imperfect production of body-heat. It is a public question, the preservation of the health and the maintenance of life in our judges and senior counsel, not unworthy of national attention.

There can be no doubt to an impartial mind that the proper ventilation of our new Law Courts is a great and pressing matter. If, in the erection of these buildings, the ventilation, alike its mode and its efficiency, be properly attended to, the experience of judges and barristers therein will make them intolerant of the arrangements in vogue elsewhere and cause them to be improved. If the arrangements adopted be as efficient as those of the Houses of Parliament, an example will be set which will be productive of the most beneficial results. But, if the plan, or rather no plan, of our old Law Courts be followed, then it is certain that the health, and with it the lives, of our legal administrators will be needlessly imperilled; and they will be subjected to a series of injurious influences which certainly are not unavoidable, and which could readily be obviated.

#### IRISH LUNATIC ASYLUMS.

THE twenty-sixth Parliamentary report on the district criminal and private lunatic asylums in Ireland, by the inspectors, opens with a comparative statement showing the number of lunatics confined in those institutions, together with those in the gaols, poorhouses, and the Government Asylum for Idiots at Lucan, at the end of the years 1875 and 1876, from which we see that there was an increase of 346 of those under detention during the latter year; but we find this partly counterbalanced by a diminution of 241 in those reported to be insane, but at large; thus leaving the not very formidable total of 105 as the increase for the year 1876, which gives a proportion of 3.50 of those mentally afflicted per 1,000 of the general population. Concerning those not under special control, but returned to the inspectors by the constabulary as insane, they appear satisfied, from their mode of collection, with the comparative accuracy of the statistics; though we fail to see how a system which apparently places in the hands of inexperienced, and presumably in many cases, uneducated, laymen, the decision of insanity can be trustworthy.

The inspectors are, happily, able to announce a decline in the idiotic element of the community, a fact which they attribute to the increased accommodation for the care of the insane, and the consequent check to the propagation of the disease.

Referring to the admissions, viz., 2,344, to the district asylums during the year under consideration, the inspectors say that, of this number, only 232 were admitted by the legitimate modes, viz., by order of the Boards of Governors or of themselves, whilst the remainder were confined either as urgent by the medical superintendents, on warrant of the Lord Lieutenant, or as dangerous lunatics, having been committed by the magistrates as such. We think this complex system open to grave objection. Doubtless, in many cases, for the benefit of the patient, as regards not only his ultimate recovery, but also his own and the safety of others, urgency demands that his transfer to an asylum should not be postponed till an order from the central authority or the Board of Governors can be obtained; and convinced of the desirability, nay more almost the necessity, of early treatment in insanity, as in other diseases, we are glad to find the inspectors advocating prompt removal to an asylum on the first manifestation of the malady. The inspectors regard, evidently, with most favour the mode of admission through the Boards of Governors, from the information afforded as to past history and chargeability. We fully

appreciate the great help in the safe and successful treatment of the insane derived from a knowledge of their past habits and tendencies; information which, from our experience of the working of Irish asylums, is often very difficult to obtain, and in that country, all the more necessary from the inadequate medical staff in most of those institutions. But in England, these desiderata are almost always readily obtained, either from the friends or through the efficiency of the poor-law system, and we cannot see why an arrangement which works so admirably in this country, cannot be made applicable to Ireland. A large proportion of those admitted as urgent and as dangerous lunatics are escorted from the country by the local constabulary, in many instances, for many miles in open common carts, perhaps on a bed of straw, handcuffed and tied down by ropes; a proceeding which cannot fail to have the most injurious effect, both moral and social, on the insane themselves, whilst it would also tend to make the friends screen the affliction of their relative till he has become outrageous or committed some insane act whereby his presence in society can no longer be tolerated. Moreover, in the case of the latter class, this delay must be directly brought about by the manifest hardship which only entitles medical men to a fee for certifying a patient insane on a "dangerous form", which in turn must be postponed till he has actually committed an outrage on the person, as if insanity cannot be exhibited in numerous ways other than violence; while, for certifying on what is known as the "ordinary form", no fee is recoverable.

Touching this subject, we regret to have to comment on the lack of knowledge of insanity in many instances displayed by those filling in the medical certificates for admission: a state of things we can only hope to see remedied when the medical schools throughout the country, following the excellent example recently set by that of Cork, establish a systematic course of instruction in mental diseases as part of the students' curriculum. This has already been done in Great Britain by most of the schools of medicine with good results, the medical superintendent of an adjoining asylum being generally chosen as lecturer, and not only giving a regular course of lectures, but also clinical instruction in the wards of his asylum. For many obvious reasons, such opening up of the wards of the Irish asylums to students must have the most beneficial effects, both to themselves, and in this we include their inmates, as well as to those instructed therein. But to the effectual carrying out of such an arrangement, it would be necessary, by the appointment of assistant medical officers, to relieve the medical superintendents of those institutions of some of their present arduous and multifarious duties, many of which in this country are carried on by their subordinate officers. For the offices of visiting physician and apothecary, offices now almost extinct in the English pauper asylums, and in many cases, we fear, little more than a sinecure in those in Ireland, might very advantageously be substituted that of assistant resident physician. It would be out of place here to point out the advantages sure to accrue from such a change; this has already been done in these columns and elsewhere, and we regret to find the inspectors silent on such a worthy subject.

The recovery-rate shows the very gratifying result of 46 per cent. on the admissions, whilst the percentage of deaths calculated on those under treatment was 7.60, both ratios bearing very favourable comparison with the recovery and death-rates of the English asylums.

There were only four suicides during the year.

From an analysis of Table I, we find that, though many of the asylums at the end of last year were either almost full, or, in some instances, excessively overcrowded, yet, calculating the total available accommodation, there was still room for upwards of 220 patients; whilst such was already, or was being, provided for 500 additional. We also see that a considerable sum of money has been expended on enlargements, internal improvements, and the acquisition of additional

lands; whilst it is reassuring to notice the inspectors, alive to the necessity for the advance of these institutions in accordance with the more enlightened treatment of insanity, saying, in speaking of increased means of comfort, etc., that "as great public institutions, they are thereby rendered more creditable to the country, and in character with the best regulated elsewhere"; we would add, also, more conducive to the recovery of their inmates, and, consequently, less expensive to the State. It is the experience of the inspectors that the comparatively recent grant from the Treasury of the weekly rate-in-aid of four shillings for each lunatic in asylums, has a tendency to diminish the liberality of the Governors, we presume, by shifting from their shoulders the responsibility to provide for their insane poor, on the principle of the more you give us the more we expect of you. This seems to be a national trait. The inspectors' remarks on this subject are somewhat obscure, and we commend their careful perusal to those interested. The districts of Derry and Armagh are still without proper asylum accommodation, owing to the parsimony of the local authorities; but, as the remedy is in the hands of the Executive, we trust it will be speedily applied.

The average weekly cost per head for 1875 varies considerably in the different asylums, rising in one, that at Clonmel, to 16s. 7½d., whilst in that at Omagh it was so low as 6s. 10½d., the total average being about 9s. 5½d.

The rate of wages is, in many cases, ridiculously low; this is more especially manifest in the case of the attendants and nurses; and it must be at once apparent that a superior class of servants cannot be induced to accept such miserable remuneration for the most arduous and trying duties. The inspectors promise a revised scale of salaries for the clerks, and we trust this will lead to an increase in the salaries not only of these and other officers, but also of those who have to bear the brunt of the battle.

On the whole, the dietary scale in the different asylums seems fairly liberal and nutritious, especially when we consider the humble and coarse fare to which most of those forming the Irish asylum population are accustomed; but we think less complex dietary tables desirable, if only for the sake of comparison.

The report of Dr. Ashe, the Superintendent of the Central Criminal Asylum at Dundrum, puts prominently before the authorities the very unsatisfactory state of the water-supply, both as regards its quality and quantity; also the dampness of the building on account of the pervious nature of the stone of which it is built, and to this he attributes the large amount of rheumatic affections of his patients.

The inspectors again draw attention to the very large proportion of the single to the married and widowed element of their charges, pointing out that it is the reverse of that prevailing in this country, but offering no explanation.

The volume is of much general interest; but we think the reports of the inspectors on the different asylums, from time to time, might be very advantageously introduced in a condensed form; and we regret to find their excellent remarks curtailed to make room for tables of comparatively little interest, even to the statistician.

THE Select Committee of the House of Commons on Lunacy Law will meet again on the 10th instant, when they will consider their report.

At the ordinary meeting of the Statistical Society, on Tuesday, March 19th, a paper will be read by Mr. C. Walford, on "The Famines of the World".

THE next meeting of the Pathological Society of London (Tuesday, the 19th instant), will be devoted to the consideration of Diseases of the Lymphatic System. Specimens will be exhibited before the meeting.

IN another column of the JOURNAL will be found the official Report of Proceedings of the Special General Meeting of the Committee of Council, which includes important resolutions relating to the question of Medical Women, the letters of Dr. Grigg, and the proposed Special General Meeting, which it was resolved to summon for Tuesday, April 2nd, at Birmingham.

THE Council of the Royal College of Surgeons England resolved, on the 14th instant, that the registration of medical students at the College be no longer required on and after this date.

THE report of the meeting of the Royal Medical and Chirurgical Society, which we publish this week, is remarkable as including a faithful report of the great English lithotritist in the largest series of cases as yet reported, we believe, by one surgeon; and these the result of the experience of a comparatively small number of years.

MR. H. SPENCER SMITH has retired from the office of Surgeon to St. Mary's Hospital, London, with which institution he has been connected from its foundation. Mr. Smith has devoted the best energies of a large part of his life to the maintenance of the interests and the development of the usefulness of this hospital and school. During all its earlier years, he spent hours daily in the school and hospital. He gave to the study of the administrative arrangements and scientific teaching the chief energies of a mind singularly well balanced, and a clear, honest, and elevated resolve. Aided by many earnest colleagues, amongst whom must be specially mentioned the regretted names of Sibson, Lane, and Gascoyen, he succeeded in at once securing for the school a recognised place amongst the most respectable of metropolitan medical schools; and this it has always retained. Mr. Spencer Smith has the satisfaction, in retiring from the hospital and school, of seeing the infant which he did so much to cherish flourishing in adult strength. Mr. Walton becomes senior surgeon in succession to Mr. Smith; and Mr. Arthur Norton is promoted to the office of surgeon, leaving a vacancy for an assistant surgeon.

THE New York papers report a painful case of death, in a dentist's chair, of a patient from whom a number of teeth had been extracted under chloroform by a dentist of Staten Island. A coroner's inquest was held, at which, according to the evidence given, the patient had died from asphyxia, by the blood in the mouth trickling into the larynx. At the *post mortem* examination, the features were blue, the brain and lungs congested; and the *post mortem* appearances altogether appeared to have been those of asphyxia from the blood running into the trachea, and not those of an ordinary chloroform death.

#### THE CONJOINT EXAMINING BOARD FOR ENGLAND.

THE Committee of Reference have almost completed the regulations for the course of education and examination under the Conjoint Scheme. We anticipate that these regulations will meet with the entire approval of the profession, inasmuch as the Committee, in drawing them up, has evidently aimed at rendering the course of education proposed of a far more practical character than it is at present, and, further, at testing by the examination, which it is proposed to divide into three parts, how far the attainments are of a practical character. We think that in both objects they have largely succeeded.

#### SMALL POX AT HARWICH.

AN occasional case of small-pox still appears at Harwich. In the last week, two cases were admitted from the town into the temporary hospital, and one from a smack on the river; this patient had, no doubt, contracted the disease in Harwich. Of the last four admitted, two were unvaccinated. Two of the cases are as severe as any that have yet been treated; one is convalescent, and one is only in the early stage, having been admitted on Wednesday. This brings the number admitted since the opening of the hospital up to seventy, of whom fifteen died, forty-five were discharged cured, and ten remain

under treatment, of whom seven are convalescent. Twelve unvaccinated cases have been admitted. Of these, two died and two remain under treatment.

#### HOSPITAL SATURDAY IN LIVERPOOL.

LAST Saturday (the 9th) was observed in Liverpool as Hospital Saturday; previously to which a large number of boxes had been sent to the various workshops and other places, where a great number of working men are employed. The total results will not be known for another week; but up to Tuesday, the treasurer had received £1,020.

#### THE GOVERNMENT MEDICAL ACTS AMENDMENT BILL.

WE understand that the Duke of Richmond will bring forward his Medical Acts Amendment Bill in the House of Lords, so soon as the Cattle Diseases Bill has been a little further advanced, so as to be out of the way. The Executive Committee of the General Medical Council meet to-day, and probably Dr. Acland will be able to lay the draft before them; but it is understood that no further particulars than those which we gave last week will be allowed to transpire until after the Duke of Richmond has made his statement in the House of Lords.

#### SURGICAL AID SOCIETY.

FROM bad beginnings sometimes good conclusions flow. The man who applied last week to Sir Robert Carden, complaining that the Surgical Aid Society had sent him all over London to seek the thirteen letters to pay the expense of repairing his leg, which meantime they kept in pawn, was an impostor in various respects. Nevertheless, his case, so far as the Surgical Aid Society was concerned, was a perfectly valid one, and is only one among many brought forward during the last four years. The presiding alderman truly said that the aid given by this society could hardly be called charity at all, and the present constitution of the society is extremely reprehensible. This is not the first time that attention has been called to this subject. During a period extending over the last three years, the Charity Reform Society have been endeavouring to obtain an amendment in the mode of administering relief to applicants by the Surgical Aid Society. In the first instance, they addressed the Treasurer through Sir Charles Trevelyan, who entered into a long correspondence with him, and brought to his notice a number of cases of previous hardship. That ended in nothing, and they then drew up a memorial and presented it to the Committee of Management; and subsequently an address was drawn up and signed by the Duke of Northumberland as President, pointing out and fully explaining the causes of the grievous injustice inflicted upon the afflicted poor by their continuance of a system of relief which had been shown to be indefensible. An earnest hope was then expressed that the Committee of the Surgical Aid Society would be good enough to reconsider the question, with a view to remedy an abuse which marred the dispensation of their charity and prevented many benevolent persons from contributing to its funds. In the event of the society declining to make a complete change, the address proposed the alternative that the subscribers should retain the power of recommending cases; and that their recommendations should be made immediately effective by relief being given directly by the Committee, with the assistance of the surgeon. A copy of that address was sent to each subscriber. Two hundred and fifty expressed sympathy with the views of the Charity Voting Reform Association, and a wish for a change. No notice was taken of the address; and, at the last annual meeting of the Surgical Aid Society, Mr. Roger Eykyn moved, "That, in the opinion of this meeting, the system of administering relief in present use by the society is capable of amendment. The Committee, therefore, is respectfully requested to draw up a scheme which would both relieve the applicants from the burthensome task of collecting letters, and also provide that cases may, after due investigation, receive prompt relief on the recommendation of a subscriber." That motion was seconded by Dr. Chepmell, and supported by Mr. Jabez Hogg, who showed how easily the immediate relief which the

society professed to give might be afforded in all cases. The Treasurer gave an assurance that the managers would give the matter full consideration in Committee, to which Mr. Eykyn was invited; and, on the strength of that assurance, the motion was withdrawn. Since then, however, we are assured, nothing has been done to mitigate the evils complained of. The society, according to the last annual report, had an income of £3,331, of which £2,500 was spent in instruments and appliances, the rest in executive expenses. It has funded property of the value of £5,000. Another society—the Provident Surgical Appliance—in 1875, with an income of £1,247:16, supplied 2,436 surgical instruments, against 1,533 supplied by the Surgical Aid Society in the same year, with an income twice as great.

#### THE INDIAN FAMINE.

A WELL-INFORMED correspondent writes to us:—"I have been taking a hurried tour through the north-west of India, and have had to notice that famine is really bad in Agra, Oude, and Rohilkund. In Agra, I saw many thousands on relief-works; and at a poor-house, the people were being brought in dead or dying, all through the day. The Rajputana States have suffered very much, and the people flock into the big towns, as they did in Madras. Small-pox is universally present amongst the distressed districts, as it was over our own famine area. The authorities of the North-West are unwilling to admit the existence of famine. They have this excuse, that good crops are on the ground, and that prices are expected to fall in the course of the next two or three months; but meanwhile the poor are dying of starvation, and the organisation for their relief, to my thinking, is wholly inadequate."

#### THE RESULTS OF RIOTING.

It appears that, in connection with the gathering in Hyde Park on Sunday, nine persons in all presented themselves for treatment at St. George's Hospital, eight of whom were suffering from broken heads and one from a fractured arm. They belonged chiefly to the rough element, and after being attended to, made the best of their way homeward.

#### COUNTEN-PRACTICE.

AN inquest was held at Lincoln on the 20th ult. on a servant who had died in one of the hotels in that city. The medical evidence showed that the girl died from small-pox. One gathers from the published report of the inquest that one of the children of the landlady arrived at Lincoln on February 2nd, and that, on February 4th, he had an eruption, which was pronounced to be chicken-pox by a chemist, who was practically the only medical attendant in this and other cases arising shortly afterwards. Within three weeks of this boy's returning to his home, no fewer than four other people in the house—two children and two servants—contracted the disease, and one of them (the subject of the inquest) was found lying dead on the floor of her room on February 19th. It is probable that all the sufferers really had small-pox, and that the disorder was imported from London with the boy. It would be interesting to know from what house, and why the boy went home at such an out-of-the-way time as February 2nd, and what before his departure from, and since his rearrival in, London, was the condition of the inmates of the house in which he resided. There is no evidence on this point, and it is only too probable that this is one of the many instances in which the inmates of a house, be they school-children or servants, are sent home the moment they fall ill. In the case of the infectious diseases, this contributes not a little to the spread of the disease about the country, and as a practice it cannot be too strongly deprecated. If the early sufferers from this so-called chicken-pox had been seen by a properly qualified medical man, it is probable that the disease would have been correctly diagnosed, and steps have been taken to prevent its spreading. Even when a medical man was called in, his opinion was not believed, and his orders that the patient was not to be left alone during the night were disobeyed, otherwise the girl would not have been found lying dead on the floor of her room when one of the maids of the house went to see her in

the morning. In any case of acute disease, one never knows at what hour delirium may set in; and it is a point, which cannot be too strongly insisted on, never to allow any patient suffering from acute disease to be left alone, no matter how quiet or rational they may seem to be. This inquiry illustrates also the results which may ensue from relying on the advice of chemists and druggists on matters of medical moment and affecting health.

#### HOW INQUESTS ARE HELD.

THE *Herts Observer* of March 2nd records an inquest held before Mr. C. C. Lewis, coroner, at Stansted. A man was found dead in a cart, and there was no evidence whatever as to how he came by his death, except that he was found hanging head foremost out of the cart, the horses walking, his head nearly touching their hind legs. There were no marks of injury on the body. Whereupon the coroner (addressing the son) said: "If the jury are satisfied your father died a natural death, will you be satisfied without having an examination made? I should not think it necessary, but if you are not satisfied we will have it done."—The son said he was quite satisfied.—The coroner said deceased had no doubt had some latent disease of the heart, or he might have had another fit. It transpired that the body had been left entirely neglected from the time of death, and the family declined to take the body or to bury it. It is perfectly obvious that such an inquiry as this is a mere farce, and that the jury had no means whatever of knowing whether their verdict was a true or a false one. In the absence of a *post mortem* examination, it was quite impossible to say how this man met his death. This is how coroners' inquests are largely held at the present time.

#### MR. GILBERT ON LONDON HOSPITALS.

A VIGOROUSLY written article, by Mr. William Gilbert, in the current number of the *Contemporary*, on the Abuse of Charity in the Administration of the five Royal Hospitals in London, will well repay perusal. Mr. Gilbert describes the first foundation of these hospitals, and the objects for which they were severally endowed, showing that they were, in fact, a model upon which the present system of Poor-law administration in the metropolis might have been formed, and that as such they did immense credit to the citizens of London, not only in the way of humane charitable feeling, but also in the shrewd common sense shown in their management. The value of their endowments originally and at the present time is next estimated, the latter, including the hospitals themselves and their sites, being reckoned as worth ten to eleven millions sterling; of which St. Bartholomew's and St. Thomas's stand for five millions. The reviewer next inquires what is the amount of benefit derived from this enormous capital, and to what extent the present application of the income is made according to the provisions of the hospital charters; and the answer is not very satisfactory. Condemning the administration of Bridewell and Christ's Hospital as injudicious and extravagant, and showing that if the average cost of patients at Bethlem were as low as that at Fisherton, £20,000 *per annum* would be saved which is now expended, Mr. Gilbert proceeds to deal with St. Bartholomew's and St. Thomas's; and this is, we venture to think, the weakest part of the whole article. It is quite right to point to the extravagant cost of the new St. Thomas's, and probably quite correct to say that an equally good hospital and site could have been obtained for one-eighth or one-tenth the money; but it is hard to see how it can justly be charged as a fault against the management of St. Bartholomew's that it is situated in the centre of what the writer admits was, in the commencement of the present century, a densely populated neighbourhood, though since that time, 120,000 of the working classes have been driven from the city. Nor can we well understand what the comparative merits of the professors of University College, St. Bartholomew's, and St. Thomas's, have to do with the question of the abuse of charity, or why the medical school attached to each of those hospitals should be spoken of as "a private speculation". The writer makes no allusion

whatever to the out-patient department, in which, unquestionably, the greatest abuses exist; and the article, though an extremely able one on the whole, shows how difficult it is for a non-medical writer to fully understand all the bearings of this complicated subject.

#### HOSPITAL FOR DISEASES OF THE THROAT AND CHEST.

MR. E. J. LUCK, the Chairman, writes to us:—"Your short notice of the special meeting of this hospital, held on the 2nd instant, contains such important omissions that, as a matter of justice to the hospital, I must ask you to permit me to state: 1. That the charges against the administration were read and answered *seriatim*; 2. That the following amendment was proposed by Mr. Gowlland, and carried unanimously: 'That whilst declining to receive the report of a private inquiry altogether unsanctioned by subscribers, this meeting, after hearing the charges that have been made against the management and the explanation, desires to express its entire confidence in the administration of the hospital, both medical and general.' Sir Charles Legard did not withdraw with Mr. Thornton and Mr. Evans, but spoke after Mr. Gowlland had moved his amendment; the Rev. Dr. Bell, the seconder of the amendment, waiving his right, as Sir Charles Legard stated that he had an important engagement elsewhere." There is nothing in this communication to affect the view that the report of a committee appointed by the President of the Hospital, the Marquis of Bute, at the request of the Patron, the Prince of Wales, and consisting of the Duke of Grafton, the Earl of Clarendon, the Earl of Dunmore, and Sir William Gull, ought to have been received and read. Any report from such a Committee so appointed was and is entitled to respectful consideration; and, in refusing to receive it, the meeting has elected to damage the hospital much more severely in public and professional estimation than by any other course which could have been devised. Such a report might be answered or refuted in any desirable manner; but not to receive it is, in our opinion, an unprecedented and improper course of proceeding.

#### SMALL-POX IN LONDON.

DURING recent weeks, small-pox has caused no death in any of the nineteen large provincial towns of England; but has continued to be fatal in London. The deaths caused by small-pox in the metropolis, which had been 39 and 54 in the two preceding weeks, declined to 34 last week; of which 22 occurred in the Metropolitan Asylum Hospitals, 2 in the Highgate Small-pox Hospital, and 10 in private dwelling-houses. Four of these deceased small-pox patients had resided in St. Pancras, 3 in Bethnal Green, 3 in Stepney, and 3 in Lambeth. Two deaths from small-pox occurred in private dwelling-houses in Mile End Old Town; and the cause of a death in Hope's Court, Walworth, was described as "probably small-pox", but was not certified by a registered medical practitioner. Of the 34 fatal cases of small-pox, 7 were certified as vaccinated, and 20 as unvaccinated; while in the remaining 7 cases the medical certificates did not give any information as to vaccination. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had declined to 137 at the beginning of October last, has since increased to 630, 651, and 667 at the end of the last three weeks; 153 new cases were admitted to these hospitals during last week, against 173 and 162 in the two previous weeks. The admissions, therefore, have shown a slight decline during the past three weeks. The Highgate Small-pox Hospital contained 61 patients on Saturday last, against 61 and 59 on the two preceding Saturdays.

#### METROPOLITAN WATER-SUPPLY.

FROM the weekly return of the Registrar-General, we learn that Dr. Frankland reports, as the result of his analyses of the waters supplied to the metropolis and some of its suburbs during February, that, taking unity to represent the average amount of organic impurity in a given volume of the Kent Company's water during the nine years ending December 1876, the proportional amount of such impurity in an equal volume of water supplied by each of the other companies, and by the

Tottenham Local Board, was: Tottenham 0.7, Colne Valley 1.0, Kent 1.1, New River 2.2, East London 3.1, Southwark 3.2, West Middlesex 3.2, Lambeth 3.3, Chelsea 3.7, and Grand Junction 3.9. The quality of the waters delivered by the five companies drawing their supply from the Thames showed an improvement upon that in the previous month, although containing, on an average, rather more than three times as much organic matter as the Kent Company's water; these waters were all efficiently filtered before delivery. The Lea water was also of much better quality than that delivered in the two previous months; this water was efficiently filtered before delivery, but contained more than twice as much organic matter as the Kent Company's water. The waters supplied by the Kent and Colne Valley Companies, and by the Tottenham Local Board, were of the usual excellent quality; they were clear, colourless, palatable, and wholesome.—Dr. Hill reports that the water supplied to Birmingham was "clear, and of greatly improved quality".—Dr. Mills reports that the Glasgow water, drawn from Loch Katrine, was "of a light brown colour, and contained muddy particles and numerous fibres".

#### THE MEDICAL SOCIETY OF LONDON.

THE 105th anniversary dinner of this Society took place on Friday, March 8th, at the Grosvenor Gallery; Dr. Buchanan, President, in the Chair. A large number of the Fellows and their friends were present. During the evening, the Fothergillian Gold Medal of the Society was presented to the successful competitor, Dr. J. Milner Fothergill, for his essay on the Antagonistic Action of Therapeutic Agents. Two silver medals were also awarded: one, to Dr. Julius Althaus, for his paper on Diseases of the Anterior Cornua of the Spinal Cord; the other, to Dr. Clement Godson, for valuable services rendered to the Society during his Secretaryship. Some excellent music, contributed by the Fellows, enlivened a most successful and pleasant evening. The following is a list of the officers and Council elected at the annual meeting on March 4th. *President*: Erasmus Wilson, Esq., F.R.S. *Vice-Presidents*: L. Sedgwick, M.D.; R. Davy, Esq., F.R.C.S.; Sir J. Fayer, K.C.S.I.; C. Godson, M.D. *Treasurer*: T. H. Hill, Esq. *Librarian*: C. Theodore Williams, M.D. *Secretaries in Ordinary*: J. A. Bloxam, Esq., F.R.C.S.; F. de Havilland Hall, M.D. *Secretary for Foreign Correspondence*: T. S. Dowse, M.D. *Council*: W. Adams, Esq.; H. Royes Bell, Esq.; Percy Boulton, M.D.; Woodhouse Braine, Esq.; J. Crichton Browne, M.D.; T. Lauder Brunton, M.D.; T. Bryant, Esq.; G. Buchanan, M.D.; A. Carpenter, M.D.; W. H. Corfield, M.D.; A. E. Durham, Esq.; D. H. Goodsall, Esq.; J. D. Heaton, M.D. (Leeds); J. Braxton Hicks, M.D.; C. Holman, M.D. (Reigate); R. J. Lee, M.D.; F. Mason, Esq.; J. C. Thorowgood, M.D.; A. Wiltshire, M.D.; J. C. Wordsworth, Esq.

### SCOTLAND.

FEVER is rife in Airdrie; eighteen cases were removed to the hospital from one tenement.

TWENTY-FOUR cases of typhoid fever and 170 of measles were reported as having occurred in Leith during the month of February. Neither of the diseases has assumed a severe form.

THE Duke of Richmond and Gordon has resolved upon supplying the village of Fochabers with water at his own expense. The water will be taken from the burn of Fochabers, and will be collected in a large cistern above the town. The works have already been commenced.

AT the instance of Dr. Polson, the Board of Supervision has communicated with the local authority of Frickheim, and pressed upon it the necessity for introducing a regular and efficient system of drainage, and also a water-supply. A meeting of the townspeople has resolved to carry out a thorough system of surface-drainage.

THE epidemic of measles in Edinburgh continues to rage severely. Last week, 22 deaths from this disease were registered, as against 15 in the week before. Fortunately, with the exception of a slight outbreak of whooping-cough, the other zymotic diseases are almost entirely absent from the city.

AT a meeting of the Board of Directors of the Fife and Kinross Lunatic Asylum, held last week, Dr. J. J. Brown, Senior Assistant-Physician at the great Asylum, Morningside, was unanimously elected Medical Superintendent, at a salary of £350 for the first year. A report from the Commissioner, Dr. Arthur Mitchell, showed that there are 289 patients at present in the asylum.

#### EDINBURGH NEW TOWN DISPENSARY.

THE annual meeting of the subscribers and managers of the Edinburgh New Town Dispensary was held last week. The medical report showed that, during the past year, 11,437 persons were treated in connection with the dispensary; 2,023 of these patients had been attended at their own homes; 308 women had been attended in confinement. It was pointed out that such benefits as were thus derived by the sick poor were only in proportion to the amount of funds subscribed and placed at the disposal of the managers, and it was hoped that the public would be induced to provide increased support to an institution which was doing so much good work.

#### ROTHESAY WATER-SUPPLY.

THE Town Council of Rothesay have been for some time considering the propriety of acquiring the water-works of the Rothesay Water Company, and, at a recent conference with the directors, the latter agreed to accept £25,000, which was equal to £12 10s. per share; and also further agreed to recommend the shareholders to confirm the bargain, provided the Council made them the offer somewhat unanimously. The Council, at a recent meeting, agreed to take a *plébiscite* of the rate-payers; and they sent out circulars showing that, at £25,000, the works would yield a fair return at once, and a good profit in another year, as the rental of Rothesay was rapidly increasing. Out of 1,718 voting-papers issued, only 794 were returned; of these, 20 were blank and 24 spoiled. Of the 750 remaining, 417 were against the purchase and 333 in favour of it. The Council have not yet decided how to act in the matter.

#### THE SETTLEMENT OF LUNATICS.

A DECISION of considerable importance to parochial boards has recently been given in the Sheriff Court, Edinburgh. An action was brought by the Inspector of Poor for the parish of Dalkeith against the Inspector of Poor for the parish of Lasswade, for advances made on behalf of a child aged nine years, an idiot, daughter of a working man, who, with the sanction of the General Board of Lunacy, was boarded in her father's house. It was decided by the Sheriff-Substitute that the girl, being an idiot, was "a lunatic as defined by statute"; and that her father, being a working man and in weak health, had a good claim for parochial relief on her account; and that the defender, as representing the parish of her settlement, was liable to the pursuer for the advances made. Appeal was made to the Sheriff-in-chief, who confirmed the judgment, with additional expenses; the Sheriff, in a note, saying that the child, being a lunatic, would have been sent in the ordinary way to an asylum; and as the sanction of the proper authorities has been given for her remaining at home instead, the parish of her settlement is bound to provide what is necessary for her proper care and treatment, just as they would have had to do had she been sent to an asylum.

#### HEALTH OF SCOTLAND.

THE returns of the Registrar-General for Scotland, for the month of February, show that there were, in the eight principal towns, 3,406 births during the month; 261 of these, or about 7.5 per cent. of the whole, were illegitimate. The rate of illegitimacy varied in the principal towns, from 3.8 per cent. in Paisley to 10.3 per cent. in Aberdeen.

The marriages, 548 in number, were 84 below the average number for February, allowance being made for the increase of population. The deaths of 2,473 persons were registered during the month; allowing for the increase of population, this number is 368 under the average of February for the last ten years. The mortality varied from the rate of 17 per 1,000 persons in Perth to that of 34 per 1,000 in Paisley. Of the whole 2,473 deaths, 1,111, or 45 per cent., were of children under five years of age. The zymotic class of diseases proved fatal to 434 persons in the eight towns, constituting 17.5 per cent. of the whole mortality. The combined prevalence and fatality of scarlatina, whooping-cough, and fever in Aberdeen, and of measles in Edinburgh, caused this rate to be exceeded in each of these towns. Whooping-cough was the most fatal of all the epidemics.

#### VACCINATION.

THE period within which vaccination is compulsory in Scotland has been altered, as far as regards the parish of Durnish, in the county of Inverness, from six months to twelve months, on the application of the Parochial Board to the Board of Supervision. The reasons for this exemption from the ordinary terms of the Act are not given in the announcement of the alteration, published by the Board of Supervision.

### IRELAND.

IT is purposed to hold a public meeting to protest against the abolition of the Wicklow County Infirmary, inasmuch as the question of closing that institution will come before the grand jury at the ensuing assizes.

MR. HENRY WALSH MAHON, late Surgeon in the Royal Navy, died at his residence near Dublin on the 9th instant, aged 69. The deceased was a Fellow of the Royal College of Surgeons, a Member of the Royal College of Physicians of London, and obtained Sir G. Blane's Gold Medal for his medical and surgical journal in 1845-6.

#### LIMERICK UNION.

Two additional cases of small-pox have occurred in the Limerick Workhouse, both patients being inmates of the hospital into which the first case had been admitted. The guardians have pointed out the desirability of isolating cases of this disease; but, in the present crowded condition of the hospital, the difficulties are considerable.

#### QUEEN'S COLLEGE, GALWAY.

DR. NICHOLAS W. COLAHAN has been appointed to the vacant Chair of Materia Medica in this College, lately held by Dr. Pye, now Professor of Anatomy. Dr. Colahan is a graduate in medicine, a Master in Surgery of the Queen's University in Ireland, and in 1870 was awarded First Senior Medical Scholarship.

#### EYRECOURT DISPENSARY DISTRICT.

AT a meeting of the Dispensary Committee held on the 1st instant, Dr. Henry O'Farrell was unanimously elected medical officer of the Eyrecourt Dispensary, in the vacancy caused by the death of Dr. Pelly. The emoluments of the post are £132:10 *per annum*, exclusive of registration and vaccination fees.

#### SEWERAGE OF BANGOR.

BANGOR is a fashionable watering-place not far from Belfast, and its sanitary condition heretofore has not been of a very favourable kind. The Newtownards Board of Guardians, acting as the rural sanitary authority, prosecuted several parties for nuisances; but no penalties were inflicted, as it was proved that no sewers existed to convey away what was objectionable. A scheme was then suggested, at a cost of £5,000; but the inhabitants opposed it as extravagant; and at last a modified plan, the expense of which will be but trifling, has been

agreed upon, which, should circumstances require it, can be extended. In the scheme first proposed, it was intended to carry the sewerage a considerable distance out into the bay; but, in the plan which has been adopted, this will not be the case.

#### THE DUBLIN HOSPITALS.

SIR DOMINIC CORRIGAN, Bart., has resigned his seat on the Board of Superintendence of the Dublin Hospitals. The Board have acknowledged his eminent services by passing the following resolution: "That we receive with extreme regret the retirement of Sir Dominic Corrigan from this Board, of which he has been an active member since its formation in the year 1856. And, further, we desire to place on record our deep sense of the valuable services he has rendered by his constant attendance at its meetings, by his wise counsel in all its deliberations, and by his practical acquaintance with the organisation and management of the institutions under its superintendence."

#### DR. STEEVENS'S HOSPITAL.

AT a meeting of the Governors of this Hospital, held on Tuesday last, Dr. Richard Bookey was appointed Physician to the Hospital, *vice* Dr. Henry Freke, resigned. Dr. Bookey has been for many years connected with the Steevens's Hospital Medical College, and has won a high reputation as a pathologist, histologist, and medical teacher. Mr. R. Johnstone, the Resident-Surgeon of the Hospital, has been appointed to succeed Dr. Grimshaw, now Senior Physician to the Hospital and Lecturer on Practice of Physic, in the Lectureship on Materia Medica.

#### SMALL-POX EPIDEMIC IN DUBLIN.

THE epidemic still continues. There are at present nearly eighty patients in Cork Street Fever Hospital, besides several others in the Hardwicke, Steevens', and Meath Hospitals. With the view of providing for a probable increase in the number of cases requiring hospital treatment, the guardians of each of the Dublin unions have appointed a committee to inquire into the available hospital accommodation; and should this prove inadequate, to consider what arrangements should be made. A plan of relieving the hospitals by providing a convalescent hospital is suggested. By this means, a large number of convalescent cases could be promptly removed from the hospitals, and they would then be able to receive and treat a large number of fresh acute cases. The subject of providing temporary accommodation for persons in houses in which contagions had occurred, during the time that these houses were being disinfected, is also under consideration. To meet the emergency caused by the rapid increase in the epidemic, the Committee of Management of Cork Street Hospital have commenced the erection of a wooden shed in order to afford additional accommodation. The following analysis of admissions to Cork Street Hospital during seven months of the present epidemic and of that of 1871-2 was submitted to the last meeting of the Dublin Sanitary Association:

August, 1871	...	4	August, 1877	...	4
September, "	...	8	September, "	...	2
October, "	...	41	October, "	...	3
November, "	...	59	November, "	...	8
December, "	...	78	December, "	...	23
January 1872	...	81	January 1878	...	19
February, "	...	90	February, "	...	76

At the same meeting, attention was directed to the Registrar-General's weekly return, from which it appeared that the Dublin death-rate was 7.5 per 1,000 higher than that of London, 11.5 higher than Glasgow, and 6.5 higher than Edinburgh. The zymotic death-rate of Dublin was 2.6 per 1,000 higher than that of twenty large English towns.

#### BELFAST UNION HOSPITAL.

THE Local Government Board, in forwarding the periodical report of their inspector, Dr. Roughan, on this union, among other matters draw attention to the dormitories, which are described as being fully occupied and in some instances overcrowded. It appears also that there is no means of ventilating the sleeping apartments at night, and

no system of closets for the convenience of the inmates; so that the air must necessarily become contaminated. Dr. Ronghan suggests that some simple and inexpensive process should be adopted for supplying a sufficient quantity of pure air to the occupants of the several wards, in which the minimum cubical space allowed for each inmate has been reached. In his supplementary report on the workhouse buildings, Dr. Ronghan observes that the drainage and sewerage of the workhouse premises generally are still most defective, especially in connection with the hospitals.

#### SMALL-POX IN BELFAST.

VERY few additional cases of small-pox have occurred since last week, and the check to the disease has been attributed to the energetic action of the sanitary staff of the borough. At a meeting last week of the Belfast guardians, a report was received from Dr. Seaton Reid, who suggested that a building should be provided as a quarantine house, into which healthy members of a family could be moved after a sick member had been sent to hospital, and where they and their clothing could be cleaned. Many lives, he considered, would be saved by such an arrangement. He also recommended that a wash-house should be erected by the sanitary authorities, where clothing from families, whether poor or rich, could be washed and disinfected when contagious diseases had occurred. This clothing was at present washed secretly by washerwomen, and in this way scarlatina and other contagious diseases were liable to be introduced into private families.

#### CHARGE OF MANSLAUGHTER AGAINST A BONE-SETTER.

AN elderly man named Hymes was last week indicted at Kilkenny Assizes for the manslaughter of one Keys in July last. Keys, it appeared, fell off a cart and sustained a trivial injury to the right arm, and was attended by the bone-setter, who applied a plaster composed principally of pitch, and bandaged the limb so tightly as to cause mortification, the patient dying a few days afterwards. Baron Dowse, in charging the jury, expressed a hope that whatever might be the result of this case, it would deter people from having recourse to the untrained and unskilled country quacks, in place of to the educated and properly qualified medical practitioners. For the poor, the Government had provided a staff, the members of which, though often miserably underpaid, brought the highest amount of skill and ability to bear upon every case committed to their treatment. Why these poor people could, then, still seek after those bone-setters, he could not tell. The jury having acquitted the prisoner, the judge hoped that for the rest of his life he would not again practise the art of medicine or surgery.

#### SCIENTIFIC LECTURES.

THE fifth lecture of this year's series of scientific lectures connected with medicine was delivered on Monday last by Dr. Grimshaw, being the first of two lectures on "The Present State of our Knowledge of the Intimate Pathology of Contagion, and its Relation to the Prevention and Cure of Zymotic Diseases". Dr. Grimshaw stated the causes which had led him to the special study of the subject of his lectures; referred to the great injury effected by contagion and infection; and, while disclaiming any title to be considered an original investigator of pathological questions, pointed out how it is the duty of every practical physician to study the observations of physiologists and pathologists, with a view of applying their precepts to practice. The lecturer then pointed out that four series of observations had been confounded by many, and inferences drawn which were not warranted by the relations which these bore to one another. These series of observations were—1. Into the nature of fermentation; 2. Into the question of spontaneous generation; 3. Into the nature of septic infection; 4. Into the nature of the contagium of specific diseases. These four series were arranged in two groups, the first two forming one group, not having any necessary connection with disease; the second group consisting of the two latter, both of which necessarily included the study

of diseases, and were essentially pathological in their nature. These different lines of inquiry were so closely connected that, although they had not any necessary connection, yet they so often interlaced that they could not be studied separately. The lecturer then proceeded to discuss the results arrived at from each series of observations. In the case of fermentation, it was shown that the relation which the study of fermentation bears to pathology is, that the septic fermentation furnished by the presence of bacteria is capable of producing the septic poison, just as vinous fermentation produces the alcoholic poison. The consideration of spontaneous generation led the lecturer to conclude that, up to the present, spontaneous generation is not proven; and that all experiments in its support have been disproved. It bears an important relation to the causes of disease; as, if spontaneous generation be possible, then we have not only to guard against the introduction of contagion from without, but also to prevent its origin within human beings. Septic infection was then considered, and the results of the introduction of the septic poison shown to depend upon the coagulation of the blood consequent on the disintegration of the blood-corpuscles by the action of the septic poison. It was shown that septic poison produced apart from any individual may cause the illness or death of that individual by direct introduction into the bloodstream, while to other cases the poison was elaborated in the wound by the growth of bacteria on the original soil provided by the discharges from the wound. This was illustrated by an account of illnesses from which the lecturer himself had suffered. The special character by which the septic poison was distinguished from the contagium of specific diseases was its incapacity for self-multiplication, and the effects produced being in direct proportion to the dose administered.

#### RATHDOWN HOSPITAL, MONKSTOWN.

THE annual meeting of the friends of this Institution was held last Monday. The report of the Managing Committee for the past year showed that there had been an increase in the annual subscriptions, principally due to the establishment of a dispensary at Kingstown, which had the effect of increasing the number of supporters and extending the usefulness of the charity. The Committee regretted to state that the County of Dublin Grand Jury had withdrawn the annual grant of £90, leaving the Institution now solely dependent upon the subscriptions of the charitable. During the year, 158 patients were admitted into hospital, whilst 1,418 were treated at Monkstown Dispensary, and at the Kingstown branch 961 cases were relieved and 112 visited at their own homes. It is proposed to erect a new wing, at a cost of £900, to provide accommodation for pay-patients, a ward for general cases, additional accommodation for nurses, and wards for isolating infectious cases. This wing will not be commenced until the entire cost has been obtained.

#### PORTUMNA UNION.

DR. COATES, medical officer of Portumna Dispensary District, at a meeting last week of the guardians of Portumna Union, submitted a list of one hundred and ninety-one names of occupiers of premises in his district which were in an unsanitary condition, being all devoid of proper accommodation, and some being unfit for human habitation. He suggested that all the parties be required to cleanse their premises, and provide privy accommodation, as well as to prepare receptacles for keeping manure-heaps at least thirty yards distant from each dwelling. These recommendations were ordered to be carried out. A report of an analysis of water obtained from a well in Abbey village showed that it was impure, containing an excessive amount of organic matter, and the Board ordered it to be closed up.

In future, medical officers are to be at liberty, in urgent cases, to attend the wives and children of soldiers married without leave, and to supply medicine for them from the public stock to a limited extent, at the discretion of the principal medical officer. In all such cases, the prescriptions are to be filed at the surgery for subsequent examination.

## MEMORIAL TO CLAUDE BERNARD.

A SUBSCRIPTION list has been opened in France for the foundation of a memorial to this illustrious physiologist, whose services to science have been such, and whose reputation in this and in other continental countries is so great, that it is unnecessary that we should add a word to indicate the cosmopolitan character of such services, or emphasise the considerations which point out the propriety of making such a memorial to some extent as cosmopolitan as were the genius which it commemorates and the services to science and humanity which it records. M. Dumontpallier, General Secretary of the Society of Biology, of which Claude Bernard was the perpetual President, is Secretary to this memorial; and, in writing to Mr. Ernest Hart to suggest the initiation of subscriptions for this purpose in England, says: "Claude Bernard, by his genius and his science, belonged to all nations; and France would be grateful to foreign *savants* who would unite in our work of admiration and gratitude to the illustrious physiologist." A small subcommittee has been formed for the purpose, consisting of Sir James Paget, Dr. J. Burdon Sanderson, Professor Humphry, Dr. Michael Foster, Mr. Ernest Hart, Mr. J. G. Romanes, and Professor Gerald Yeo of King's College, to the latter of whom subscriptions may be sent.

We are authorised to add that the Physiological Society of Great Britain, which, it will be seen, has added its Honorary Secretaries to the Subcommittee, associates itself with this movement, and will officially communicate a letter of sympathy to the Société de Biologie in Paris.

## THE MEDICAL DEPARTMENT OF THE CONVICT SERVICE.

AT the commencement of the financial year, the New Prisons Act will come into operation; it is, therefore, convenient that the claims of the Medical Department of the Convict Service should at this season be brought under the notice of our readers. Several letters have already appeared in the medical journals, pointing out the duties and responsibilities of the department and the total inadequacy of the remuneration. The small number of appointments, in comparison with that which is found in other branches of the Government service—for example, the Army, Navy, and Civil Service—is one great reason why the claims of the surgeons are not sufficiently recognised. The explanation given by the authorities, that "the supply equals the demand", is simply because the vacancies are not numerous; and when one does occur, a candidate is obtained, although often with difficulty, of a class of men who are willing, while young, to catch at an appointment which, being under Government, insures directly a certain, however inadequate, remuneration. But the shoe begins to pinch after several years' service, when the maximum salary allowed (£400 a year) is arrived at, and private practice is prohibited. The responsibility and arduous nature of the duties may to some extent be realised when it is remembered that, whenever a complaint is made by a prisoner or his friends, or a death occurs during imprisonment, the doctor is the one upon whom the onus rests. A prisoner is stated to have been unfit for the labour, or insufficiently fed, or his disease was not taken into consideration; the executive department shrug their shoulders, a committee of inquiry is forthwith appointed, the doctor is responsible, and before long his name figures in the debates in the House of Commons. In a Public Works Prison, containing over 1,500 prisoners, the annual number of complaining sick prescribed for amounts to 38,700; the number admitted to hospital exceeds 1,300. By these figures, it may be judged how difficult it is to discriminate between the real and the feigned; and those who are the most experienced in the practice of our art will know best how to make allowances for imperfections in this respect. There are no half measures. A prisoner states that he cannot work, and the medical officer has at once to say in writing whether he is fit or not. Not a single day's bread-and-water, or punishment of any kind, can be inflicted without the signature of the surgeon. If a decided course be not at once adopted, the number of prisoners shirking their work becomes overwhelming, and the machinery comes to a standstill. The fact that so few mistakes are made speaks a good deal for the efficiency of the medical staff of the service.

But, if the opinion of the surgeon be so necessary to the proper management and working of a convict prison, why is he not more

liberally paid? It is natural that every man, whatever his calling, should strive to attain a competency as his length of service increases, and it is unfair that no prize whatever should be within the reach of those who do their duty zealously. The maximum salary is arrived at after five years' service, and there the unfortunate doctor is doomed to remain; while his pension at the end, being a fraction of the small pay while on full duty, becomes a mere nothing. It is of the first importance to obtain candidates who are properly fitted for these appointments, and it is a mistake to be satisfied with young men from the hospitals, who are inexperienced in clinical work. If the Government wish to attract good men, they must offer adequate remuneration; and an improvement in the scale of pay, such as has been recently granted to the clerks in the Civil Service—especially a steady increment, however small, as a reward for efficient services—would go a long way to dispel the present dissatisfaction and loss of heart which pervade the whole department.

At Woking Invalid Prison, where the number of patients always in hospital is over 150, besides many other invalids, and about 100 certified lunatics, the surgeon has less pay than the governor, who has no responsibility whatever. At present, all the good appointments in the service are kept for the executive department, and the medical officers are completely left in the background. We trust, however, that, when the new Bill comes into force, more consideration will be shown to this deserving body of professional men, who spend their lifetime in ministering to the wants of such a thankless class of men as convicts.

## HOSPITAL AND DISPENSARY MANAGEMENT.

## SELF-SUPPORTING MEDICAL SOCIETY AT EDGBASTON.

AT the present time, when the provident system is attracting much attention at Birmingham, the following extract from the *Charity Organisation Reporter* of January 10th will be read with interest.

"The following is a statement we have lately had sent us of a medical society which has been self-supporting for twenty-one years. Mr. T. Britton, 101, Morville Street, Ladywood, is the acting manager:—'The necessity of a well conducted self-supporting medical society has long been an acknowledged want in Birmingham by thousands of families, in which they could have the benefit of medical attendance, with medicine, in the hour of sickness, by a small weekly contribution. This necessity has happily been supplied to the numerous families of Edgbaston and Ladywood by that well-known and long established society the Edgbaston Medical Self-Supporting, which has given general satisfaction to all its members, by the prompt attention and skilful treatment of the gentlemen who are medical officers of the society. The manager has resolved, after twenty-one years of experience, by this prospectus to make it known to those families who have not already heard of its advantages, and to urge upon them the necessity of at once enrolling themselves as members. The payments being of so moderate a character—one penny weekly—brings it within the means of all. Persons in health taken from one to fifty years of age.'

## "THE NATIONAL DISPENSARY."

THE *Kilburn Times* of December 28th contains the following advertisement.

"The National Dispensary, 14, Lismore Circus, Haverstock Hill, open daily from 11 to 1, and 6 to 9 P.M., and on Sundays from 6 to 9 P.M. only. Conducted by Dr. E. A. Lewis and qualified assistants. For qualifications, *vide Medical Register*. The dispensary has for its object the treatment, by legally qualified medical men, of all diseases, acute or chronic, medical or surgical, at so moderate a cost as to be within the reach of all. Experience has shown that one-half the severest cases in our hospitals would never have had occasion to be received there, had the patients in the first instance sought skilled advice; and especially in cases of *babies and young children*, thousands of lives can be saved annually by timely treatment. Diseases of women and children are made a special feature here. Accouchements attended—fee, from 10s. 6d., payable in advance. Private consultations, operations, etc., as per arrangement. Yearly subscriptions, £1 1s."

This advertisement reminds us of a class of institutions which are not much in favour with the profession. What is the nature of this "National Dispensary"? It is like, and yet unlike, the many spurious self-supporting dispensaries which have sprung out of the provident movement. We are all familiar with "shilling dispensaries", but this is a "guinea dispensary". As the dispensary is intended for the class who frequent hospitals, we may ask how is the guinea to be paid—all at once, or by instalments? Perhaps these are to be the same as at the regular provident dispensaries of the neighbourhood, and with which, by the way, Kilburn and Haverstock Hill are particularly well supplied. But the midwifery fee is so low (10s. 6d.), that the "National Dispensary" would seem to underbid both the provident dispensaries and the medical men of the district. A national institution should not do anything so ungenerous; on the other hand, the time which Dr. E. A. Lewis proposes to give to his dispensary is lavish beyond all precedent. We are afraid that if they have many patients, Dr. E. A. Lewis and the "legally qualified medical men" who assist him will be harassed to death, and quite unable to carry on the branch dispensaries at Holloway and Kilburn which they propose to open shortly.

## ASSOCIATION INTELLIGENCE.

### NOTICE OF EXTRAORDINARY GENERAL MEETING.

NOTICE is hereby given, that an Extraordinary General Meeting will be held at the Queen's Hotel, Birmingham, on Tuesday, the 2nd day of April next, at three o'clock in the afternoon:

1. To consider requisition received from members of the Metropolitan Counties Branch, of which the following is a copy.

*To the President and Committee of the Council of the British Medical Association.*

Gentlemen,—We hereby request you to make arrangements for submitting the following resolutions to an early special general meeting of the British Medical Association.

- "1. That this meeting is of opinion that the Reports of the Proceedings of the Committee of Council should be published in as complete and intelligible a form as is consistent with the conduct of business; and that in no case should important resolutions affecting the general interests of the Association be omitted.
  - "2. That this meeting desires to express its opinion that in the selection of a house for the Association, it is desirable that the Council, Committee, and consulting rooms should be separate from the printing and publishing offices."
2. To consider the privileges of lady-members.

By order of the Committee of Council.

FRANCIS FOWKE, *General Secretary.*

London, March 13th, 1878.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETING.

THE next meeting is appointed to be held at St. Bartholomew's Hospital, Rochester, on Tuesday, March 19th, at 4.30 P.M.: Dr. BURNS, R.N., in the Chair.

Dinner will be provided at the Bull Hotel, Rochester, at 6.15 P.M.

Papers have been promised by A. W. Nankivell, Esq., on Acute Necrosis; and by J. Thoresby Jones, Esq., on a Case of Displacement of the Sacrum.

FREDERICK JAMES BROWN, M.D., *Honorary Secretary.*

Rochester, March 5th, 1878.

### SOUTHERN BRANCH.

AN ordinary meeting of the above Branch will be held at the George Hotel, Portsmouth, on Wednesday, March 20th, 1878, at 4.15 P.M.

The following papers are expected.

1. Mr. Parson: Large Cystic Sarcoma of Testicle.
  2. Dr. Knott: Notes on a Case of Pleurisy.
  3. W. E. Saunders, Esq., A.M.D.: The Treatment of Intermittent Fever by Nitrite of Amyl.
- Dinner will be provided at 6.30 P.M. Charge, 6s., exclusive of wine.

Members intending to be present at the dinner are requested to send in their names on or before Monday, March 18th.

J. WARD COUSINS, *Honorary Secretary.*

Southsea, March 12th, 1878.

### YORKSHIRE BRANCH.

THE spring meeting of this Branch will be held at the Infirmary, Rotherham, on Wednesday, March 27th, at 3 P.M.

Members wishing to read papers or bring forward cases are requested at once to communicate with the Secretary.

After the meeting, the members will dine together at the Ship Hotel at 5 P.M. Tickets (exclusive of wine) 6s. 6d. each.

W. PROCTER, M.D., *Honorary Secretary.*

York, February 26th, 1878.

### METROPOLITAN COUNTIES BRANCH.

A GENERAL meeting of this Branch will be held at 11, Chandos Street, Cavendish Square, on Wednesday, March 27th, at 8 P.M., when the discussion of Mr. Holmes's paper on Provident Dispensaries will be resumed.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*  
W. CHAPMAN GRIGG, M.D. }

London, March 13th, 1878.

### SOUTH-EASTERN BRANCH: WEST SURREY DISTRICT MEETINGS.

The next meeting of the above District will be held at the Surrey County Hospital, Guildford, on Thursday, March 21st, at 3.45 P.M.: HENRY TAYLOR, Esq., in the Chair.

The following papers have been promised.

1. Mr. Henry Smith: On Surgical Interference in Malignant Growths.
2. Mr. Thomas Butler: A Case of interest in the Hospital.
3. Mr. A. A. Napper: A Case of Complete Separation of the Gall-Bladder from the Liver.
4. Mr. Charles Sells: A Case of Ovariectomy.
5. Mr. Henry Taylor will show a Tumour of the Ovary, and a Tumour of the Pituitary Body.

Dinner will be provided at the White Lion Hotel, at 6 P.M. precisely. Charge, 7s., exclusive of wine.

A. ARTHUR NAPPER, *Honorary Secretary.*

Cranleigh, March 7th, 1878.

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE next meeting will be held in the Council Chamber of the Town Hall, Dover (not at the Harp, as announced in last week's JOURNAL), on Thursday, March 21st, at 3 o'clock. Dr. ROBINSON will preside.

Dinner will be provided at the Harp Hotel, at 5 o'clock precisely.

Notices have been received of the following communications to be read to the meeting.

1. Mr. Clement Walter: Hydrophobia.
2. Mr. Teevan: On the Importance of an Early Diagnosis of Stone in the Bladder.
3. Mr. Wachter: Case of Foreign Body in the Female Bladder.
4. Mr. Coke: Case of Compound Displacement of Shaft of Tibia from its Lower Epiphysis: Reduction, with Successful Result.

Gentlemen who intend to be present at the dinner are requested to inform the Honorary Secretary on or before Tuesday, the 19th instant.

WM. KNIGHT TREVES, *Honorary Secretary.*

Margate, March 11th, 1878.

### SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

THE first meeting of the above District for the present year will be held at the New Kentish Hotel, Tunbridge Wells, on Friday, March 29th, at 3 P.M.: F. MANSEY, Esq., of Tunbridge Wells, in the Chair.

Dinner at 5 o'clock. Charge, 6s., exclusive of wine.

Members intending to read papers, or offer communications, are requested to forward notice of the same, not later than Thursday, the 21st instant, to the Honorary Secretary, in order that they may be inserted in the circular convening the meeting.

The following have been promised.

1. Dr. Fairlie Clarke: Case of Diffused Melanotic Cancer.
2. Cases by the Chairman: a. Spindle-celled Sarcoma; b. Long-standing Hydrocele cured by Injections of Port-wine and Spirits of Wine.

THOMAS TROLLOPE, M.D., *Honorary Secretary.*

9, Maze Hill, St. Leonard's-on-Sea, March 12th, 1878.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE next meeting of this Branch will be held at Carmarthen, on Thursday, April 4th.

Members desiring to read papers, etc., are requested to forward the titles to Dr. Sheen, Cardiff, before the 28th instant.

ANDREW DAVIES, M.D. } *Honorary Secretaries.*  
ALFRED SHEEN, M.D. }

March 11th, 1878.

### NORTH OF ENGLAND BRANCH.

THE spring meeting of this Branch will be held at Hexham, on Thursday, April 25th.

Gentlemen who are desirous of reading papers, introducing patients, exhibiting pathological specimens, or making other communications, are requested to signify their intention to the Secretary at their earliest convenience.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, March 12th, 1878.

## PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

At a meeting of the Committee of Council, held at the Freemasons' Tavern, Great Queen Street, London, on Wednesday, the 13th day of March, 1878, specially convened to consider the correspondence in the JOURNAL, relative to the published Proceedings of the Committee of Council, and also the question of female members: Present, Dr. R. W. FALCONER (President of Council), in the Chair, Dr. Eason Wilkinson (President), Mr. W. D. Husband (Treasurer), Dr. T. Clifford Allbutt, Mr. Alfred Baker, Dr. M. De Bartolomé, Dr. L. Borchardt, Dr. Alfred Carpenter, Dr. C. Chadwick, Dr. J. W. Cousins, Dr. A. Davies, Dr. Eastwood, Mr. W. A. Elliston, Dr. B. Foster, Dr. W. C. Grigg, Dr. C. Holman, Mr. J. R. Humphreys, Mr. A. Jackson, Dr. D. J. Leech, Dr. E. Lund, Dr. F. E. Manby, Dr. E. Morris, Mr. R. H. B. Nicholson, Dr. C. Parsons, Dr. R. C. Shettle, Dr. E. H. Sieveking, Dr. A. P. Stewart, Dr. W. F. Wade, Dr. E. Waters, and Mr. C. G. Wheelhouse.

Read letters of apology from Mr. Wright Baker of Derby, Mr. Calender, F.R.S., Dr. Paget of Cambridge, Dr. Duffey of Dublin, and Mr. Mason of Bath.

Dr. Grigg handed in his protest against the meeting, of which the following is a copy:

"That, inasmuch as the present special meeting is not convened in accordance with the conditions specified in By-law 27 of the Association, page 19, this meeting is therefore illegal, and cannot proceed to business. (Signed) "W. C. GRIGG, M.D.,

"Hon. Sec. Metropolitan Counties Branch.

"6, Curzon Street, Mayfair, March 13th, 1878."

Moved by Dr. DE BARTOLOMÉ, seconded by Mr. HUMPHREYS, and

Resolved: That this meeting be considered as called legally, and that the Committee of Council do now proceed to the next business.

The PRESIDENT of the Council then called upon Dr. Grigg to state his reasons for holding that, in the selection of the house for the Association, it is desirable that the Council, Committee, and consulting rooms should be separate from the printing and publishing offices.

Dr. GRIGG then gave his reasons, whereupon it was moved by Dr. WADE, seconded by Dr. ALLBUTT, and

Resolved unanimously: That the following statement be published in the JOURNAL.

"The increasing business of the Association has long required more commodious and more central offices, and, in order to meet this want, the Committee of Council have taken the premises in the Strand. The new offices will enable the whole of the ordinary work of the Association to be conducted under one roof: an arrangement which, in the experience of the Committee of Council, will be more than ever necessary in view of the extended operations of the Association; and the locality of the offices, it is thought, will contribute to the success of the JOURNAL as an advertising medium, and thus add to the revenue of the Association. The desirability of the Association undertaking what printers call the composition of the JOURNAL has been pressed upon the Committee of Council in special reports by the editor and by the business manager of the Association, and, after an exhaustive inquiry, the pecuniary advantage of the course has been so conclusively proved, that the Committee of Council feel sure it will receive the cordial support of the Association when fully submitted to the members, as it will be in the annual report."

Moved by Dr. GRIGG, and (seconded by Mr. R. H. B. Nicholson pro forma):

1. That (a) an amended Report of the Proceedings of the Committee of Council of January the 9th be published, including a copy of the amendment moved by Mr. Husband and seconded by Dr. Eastwood in reference to Dr. Wilson Fox's letter; (b) a copy of the Report of the Committee on Habitual Drunkards; and (c) the regulations for the better management of annual meetings.

2. That, in view of the resolution of the Metropolitan Counties Branch and of similar resolutions included in the requisition for a special general meeting, signed by upwards of two hundred and thirty members of the Metropolitan Counties Branch, the Subcommittee upon the new premises be instructed to stay any further proceedings or expenditure until after the special general meeting has expressed an opinion on those resolutions.

The resolution having been put from the chair, the same was declared to be lost, no vote being recorded in its favour.

Moved by Mr. HUSBAND, seconded by Mr. HUMPHREYS, and Resolved unanimously: That the Committee of Council, having considered the statements of Dr. Grigg respecting the publication of the Proceedings of the Committee of Council, fully approve of the conduct of the President of Council.

Read, requisition from the members of the Metropolitan Counties Branch, of which the following is a copy.

To the President and Committee of the Council of the British Medical Association.

Gentlemen,—We hereby request you to make arrangements for submitting the following resolutions to an early special general meeting of the British Medical Association.

"1. That this meeting is of opinion that the Reports of the Proceedings of the Committee of Council should be published in as complete and intelligible a form as is consistent with the conduct of business; and that in no case should important resolutions affecting the general interests of the Association be omitted.

"2. That this meeting desires to express its opinion that in the selection of a house for the Association, it is desirable that the Council, Committee and consulting rooms should be separate from the printing and publishing offices."

Moved by Mr. HUSBAND, seconded by Dr. BORCHARDT, and

Resolved unanimously: That, in compliance with the requisition received, a Special General Meeting be held at Birmingham on April 2nd, at three o'clock.

Read letters from Dr. Wilson Fox and Sir William Jenner, stating their intention of resigning in consequence of lady-members being permitted to attend the meetings of the Association.

Moved by Dr. EASTWOOD, seconded by Dr. GRIGG, and resolved unanimously:

"That the Committee of Council is of opinion that women should not be admitted as members of the Association, and that a by-law be submitted to that effect to the annual meeting."

Moved by Dr. STEWART, and

Resolved: That the consideration of the privileges of lady-members be referred to the special meeting of the Association, to be held at Birmingham.

## METROPOLITAN COUNTIES BRANCH: GENERAL MEETING.

A GENERAL meeting of the Metropolitan Counties Branch was held at 11, Chandos Street, Cavendish Square, on Wednesday, February 27th, at 8 P.M.; SEPTIMUS W. SIBLEY, Esq., President, in the Chair.

*Treasurer of the Branch.*—The PRESIDENT announced that, since the last meeting of the Branch, the Treasurer, Robert Dunn, Esq., had died. The Council had unanimously passed a resolution, expressing regret at the loss they had sustained, and had forwarded it to the family of the late Mr. Dunn. They had also appointed Dr. Walter Dickson to act as Treasurer of the Branch until the next annual meeting.

## PROVIDENT DISPENSARIES.

Mr. T. HOLMES read a paper on Provident Dispensaries, which is published at page 355.

Mr. R. PARAMORE said that the subject was full of importance and interest to the general practitioners of medicine. He had heard it stated that the provident system should take hold on the upper stratum of the artisan class. But this class supplied most of the patients of many of the medical men in London, and contributed many thousands of pounds to the profession. If this source of income were taken from the medical men, many of them would suffer; and the provident system would do much harm if it were made to include the class to which he had referred. The club system had been much increased; but he thought that club-practice was, as a rule, degrading, and that it was impossible to conduct it with satisfaction when the payments were so low as four shillings a year. The hospital out-patient system was indeed defective; but he feared that, if any sweeping change were made, the evil might be increased. The provident system would no doubt do good; but it was also liable to do harm. Some practitioners might get the appointments, while others would be excluded.

Mr. NELSON HARDY said that, agreeing in the main with Mr. Holmes, he thought that, with regard to one point to which he had referred, in his (Mr. Hardy's) opinion, it was desirable to look at the matter not altogether from a hospital physician's or surgeon's point of view, but more broadly as it affected the whole profession, and especially the general practitioners. The question brought before the meeting by Mr. Holmes was part of a very large one; but Mr. Hardy would restrict himself almost entirely to stating some facts with reference to the remuneration of medical officers, just glancing, if possible, at the question, how far the system of provident dispensaries had been successful in remedying the acknowledged evils of the out-patient system in London. In a conversation he had last August, at the meeting of the British Medical Association, with one who had been working and writing on this subject longer probably than any one else in this Branch, or indeed in the profession, Dr. A. P. Stewart, he mentioned to Mr. Hardy that Dr. William Farr had expressed an opinion that, at some future time, it might possibly be arranged that a large part of the

community might be provided with medical attendance on the plan of health-assurance, which, with mutual combination, is the essential principle of provident dispensaries. The idea struck Mr. Hardy at the time as being a very good one, and he had lately communicated with Dr. Farr on the subject; and he had, in reply, sent a copy of his letter prefixed to the *Supplement to the Thirty-Fifth Annual Report of the Registrar-General*, containing his views, at the same time expressing his deep interest in the question. These were some of Dr. Farr's figures. In England, in 1871, the deaths were 514,879. This implied that 1,029,758 persons were constantly ill from diseases of some severity; or, in other words, that there were annually 12,357,096 patients ill, on an average, for a month each. These figures were already large; but, when it was considered that for each one of a number of persons ill for a month, on an average, there was at least another ill for but a few days, it would be found that there were about 24,000,000 patients, or cases of illness, where medical attendance had to be provided for. There were three principal ways in which such medical attendance might be provided, namely: 1. Private practice, in which fees proportionate to the means of the patient and the reputation of the practitioner were paid; 2. Friendly societies and clubs, in which, for a fixed sum per member per year, the doctor undertakes to supply medical attendance and medicines; 3. The Poor-law medical department, which paid, often very inadequately, medical men for attending on those who could not pay for themselves. (Mr. Hardy purposely omitted reference to the gratuitous out-patient system, beyond saying that it was not, in his opinion, a mode in which any large portion of the population ought to receive medical advice.) In discussing the question, whether the payments to medical officers under the present provident dispensary system were adequate or not, it would be well not to take too high a standard. It would be manifestly unfair to compare the receipts from this source with those from private practice; and he was quite content to take the best clubs and Poor-law medical officers' salaries, such as they were in London, as the standard of comparison. He did not suppose that any member of the profession would wish to set up clubs at 2s. 6d. a head *per annum*, or Poor-law districts where the salary was so small as £15 a year, as models that should be imitated by provident dispensaries. At the present time, in the metropolitan district, thanks to the exertions of Dr. Joseph Rogers, Mr. Ernest Hart, and others, the average salary of a Poor-law medical officer was, he believed, not less than £100 a year. For this he had to attend at certain hours in the day at the dispensary provided, and to visit the sick poor who required it, but he had nothing to do with the drugs or their dispensing. But, on examining the statistics of provident dispensaries, it would be found that in London, according to the statistical table prepared by Dr. Ford Anderson, and published as an appendix to Sir C. Trevelyan's paper already referred to by Mr. Holmes, that there were, in April 1877, twenty-seven provident dispensaries; and of these, in thirteen the statistics, with regard to salaries, midwifery fees, and number of medical men, were given with sufficient fulness to enable the following facts to be stated. In but one of these thirteen dispensaries (and but three of the whole twenty-seven) did the amount divided between the medical officers average £100 a year each (excluding, of course, midwifery fees, mostly at 10s. each). In one it was as low as £15. Taking the total amount paid to medical men in these thirteen dispensaries, and distributing it equally amongst the forty-four medical officers, it would give but £45 *per annum* to each of them; and this not for the most part in newly-established institutions, but including some of the oldest and best provident dispensaries in London, such as Camberwell, Paddington, and St. John's Wood. Dr. Rogers, speaking in 1873 of the salaries of Poor-law medical officers, justly complained that there was no uniformity in them; that the rate of payment varied in different places from an average of 8d. per case of illness to 7s. per case. In the table of provident dispensaries already quoted, after deducting midwifery fees of 10s. each, the matter stood as follows. At Paddington, 7,146 cases of illness were treated, and £200 was paid to the medical men, being not quite 7d. per case. At St. John's Wood, 3,294 cases were treated and £154 paid, being 11d. per case. At Hampstead, for 960 cases £79 16s. was paid, or 1s. 8d. per case. At Camberwell, 11,190 cases were treated and £590 paid, or 1s. per case. In short, at five provident dispensaries, of which full statistics were given, nearly 25,000 cases of illness were treated by qualified medical men for rather less than 1s. a case. In making these calculations, he had not selected particular dispensaries, but had taken all of which full particulars were given in Dr. Ford Anderson's table. He would take another standard of comparison. The friendly societies, under the various names of Oddfellows, Foresters, and other clubs, were organised on a self-supporting basis, and the best of them paid 4s. or 5s. a head per year to their medical officers, for which, it was true, medicine had to be provided; but, as they only admitted adult males, the proportion

of cases of illness was very much less than where women and children were taken. Dr. Farr alluded to this system of contract as follows. "It is already the custom of the proprietors of mines, and of other great works, to engage medical men to attend their workpeople by the year. This practice is laudable and deserves extension. The friendly societies contract for medical attendance, the only fault being that the terms are too low to insure the utmost efficiency." (*Supplement to the Thirty-Fifth Annual Report of the Registrar-General*, page lxxxi.) Dr. Farr was probably alluding to those clubs to which Mr. Hardy had referred as paying so low as 2s. 6d. per head *per annum*; but what would he have said if he had learned that, in the most successful provident dispensary in London—namely, that at Camberwell—the contract price for medical attendance, or at least the sum actually paid for such attendance, exclusive of midwifery fees, was at the rate of 1s. 4½d. per head *per annum*; while at the next largest (that at Battersea), which, however, it is but fair to add, had only been "converted" in 1876, it was very much lower? He would only further direct attention to a statement made in the column of remarks in Dr. Ford Anderson's table with reference to the dispensary at Heath Street, Hammersmith, that "a local chemist dispenses at 1s. 6d. per head *per annum*, including medicine". Here was another standard of comparison, which surely was low enough; and if any one were content with such a standard, he need not dwell upon the trifling difference between 1s. 6d. and 1s. 4½d. in favour of the chemist. The question which he wished to bring before this Branch was: Ought we, as members of an honourable profession, to be content with such payments as these? Does 7d. per case of illness, and 1s. 4½d. per member *per annum* remunerate a medical man properly for attendance on a provident patient, and if so, how can we ask more for attending club patients or paupers? Is £15 a year a sufficient recompense for attending two or three times a week at a dispensary at stated hours and being liable to be called to cases of illness at any hour of the day or night? Would any business man undertake to attend, or even let one of his clerks attend to the most routine work on such terms? The answer which he thought should be given to such questions could be easily guessed—but it might be as well to state it explicitly—he did not consider that the salary of any provident dispensary doctor should be less than £100 a year; or, if less, he would have him paid at the rate of 5s. per member or 2s. 6d. per case of illness, at the least. If the provident system could not yield such payments, he would consider it unworthy of adoption; but his belief was that if the present out-patient system were modified as Mr. Holmes proposed, there would be room for provident dispensaries on a scale of which there was now little idea. It was not to the provident principle that he objected, but to people being taught providence at the expense of our profession, as they used to be and are still taught to consider it a charity for medical men to give away their services in the most improvident manner. He had no time to refer to the question how far the system of provident dispensaries had become successful in remedying the evils of the out-patient system. It seemed to him that the number of patients at our large hospitals went on continually increasing, in spite of the fact that since 1870 the number of struggling, semi-charitable, semi-provident dispensaries in London have now doubled. He hoped that before the Branch pronounced any opinion in favour of a further increase, it would make sure that some of the worst features of poor-law and club medical practice would not be reproduced in these institutions.

Dr. JOSEPH ROGERS said that it was difficult to work out such a scheme as was propounded in Mr. Holmes's paper. He was present some years ago at a meeting in the rooms of the Royal Medical and Chirurgical Society, where the question of the out-patient department of hospitals was considered. When the facts were stated, great disgust was expressed, and a committee was appointed; but very few of the members afterwards met; and it was only through the energy of Sir Charles Trevelyan, Mr. Holmes, and others, that the subject was kept in sight at all. Mr. Holmes had said that well-to-do persons were probably deterred from attending the out-door departments; but he (Dr. Rogers) knew that ladies would put on their servants' dresses and risk the inconvenience of the waiting-room, in order to obtain gratuitous attendance. It was not possible, by the provident dispensary system, to touch the special hospitals, which did a great deal of damage to the general practitioner, and took in persons above the artisan class. About two months ago, he attempted to originate a provident dispensary (not as a source of emolument to himself), and had a promise of assistance from the Charity Organisation Society. On asking the assistance of a large employer of labour, he was informed by this gentleman that he could not aid him, as he was connected with a general dispensary. It was these gratuitous dispensaries that prevented the provident system from being carried out in the metropolitan dis-

trict. Since the establishment of the poor-law dispensaries, he had watched them with interest; and he had found that in all cases in which the poor-law dispensaries came into contact with the out-patient departments of hospitals, there were no patients but those who required articles of food or other extra matters; while on the out districts, where there were no hospitals, the poor-law medical officers at the dispensaries were overwhelmed with work.

The Reverend Mr. KEMP said he would have been glad if Dr. Rogers had not only spoken of the evils of free dispensaries, but had shown how they were to be suppressed. He concurred with the general principles laid down by Mr. Holmes as to the management of provident dispensaries; but two or three considerations had been overlooked. In the establishment of provident dispensaries, something approaching to legislative compulsion would, he thought, have to be adopted. It was not possible to deal with all localities where the sick poor required attendance. He would ask whether, if the free dispensary were got rid of in any district, the poor could contribute to a provident dispensary? It must be remembered that they were very migratory, and unless some plan could be arranged for returning their money (which would be very difficult), he did not think they would subscribe with the risk of losing the benefits of membership on removing to a district where there was probably no provident dispensary. It was very difficult to excite habits of providence under any circumstances, and still more in the conditions of which he had spoken. The establishment of provident dispensaries would be attended with the formation of a class of patients between the members of these dispensaries and the proper subjects of poor-law relief. What was to become of that numerous class which, though not paupers, could not afford to pay for medical attendance? They would be driven to the workhouse dispensaries. It was quite true that a man was not legally pauperised by merely going to a workhouse dispensary; but the independent spirit of the working-men would lead them to shrink from this, because they would thereby be morally, though not legally, pauperised. He believed that most persons, in making an estimate of their yearly expenditure, did not take the doctor's bill into account; and could it be expected that working men would be able to lay by sufficient out of their earnings to pay for medical attendance? He would be glad to have advice as to the best plan to be followed in the rearrangement of the dispensary in King Street, and how a sufficient number of poor could be got to join a provident dispensary.

Dr. SQUIRE advocated the extension of the provident system, and the adoption of it by the old free dispensaries, where possible. The Leicester experience showed this to be a good way of commencement. The St. George's Provident Dispensary, to which he was attached as physician, was becoming a great success; at first, it suffered from the proximity of the old St. George's and St. James's Dispensary; their limits were strictly defined, and no resident out of the St. George's district was admitted to the benefits of the new system; yet, in three years, the number of members had increased from two thousand six hundred and sixty-four to three thousand eight hundred and thirty-nine, and their payments from £110 to £183; the number of members visited at their own homes had more than doubled. The annual payment from the members had always met the cost of drugs and appliances; but, as more regular subscribers were added, it would become self-supporting. The benefits of provident dispensaries should be spread, and the crowding of out-patients in the hospitals checked; and, though the two ends, when gained, would help to maintain each other, they were totally distinct and must be reached by different ways and means. Provident dispensaries must not be joined or affiliated to large hospitals. Cases would be sent from them to the hospitals, just as they were from every department of medical practice; but one great object of the dispensary must be to make its medical aid as perfect as possible. Provident dispensaries should not be founded merely to relieve the out-patient department at hospitals; this may be one of their indirect results, but should not be considered a chief object. The foremost consideration in forming provident dispensaries was that of promoting a great medical charity; of helping those who helped themselves. It was important to enlist aid from without in support of this object just as it was given in support of education. He agreed with Mr. Holmes, that out-patients at hospitals should be restricted by the recommendations of doctors as well as of subscribers. But this department was of more use in showing students the ordinary run of cases than in making it a consultative department for the practitioners of the district.

Dr. WALKER said that the present system of medical charity did not tend to elevate, but rather to pauperise. There ought to be a central committee for forming provident dispensaries throughout London, with local committees of medical men and others. He believed that if they were established the profession would receive the money which

it ought to. The dispensaries should be so managed as to gain the sympathy of all the medical men in the respective districts, each of whom should be allowed to have his share of duty in his turn. He agreed with Mr. Holmes that the provident dispensaries should be the outposts of hospitals. In cases of consultation, there should be a fee paid to a general fund, which the physicians and surgeons should divide at the end of the year.

Mr. WILLIAM SEDGWICK had been for many years connected with a provident dispensary. The difficulty as to the intermediate class had been met by placing in the hands of subscribers the privilege of nominating patients in cases of necessity.

Dr. E. T. WATKINS said that, in a provident dispensary with which he was connected, subscribers had formerly the privilege of nominating patients. The result was that the institution was swamped with old and incurable cases, and no one received a penny from it. He had procured the making of regulations that candidates for admission should be examined as to the state of their health, and that the privilege of subscribers to nominate patients should be limited. The provident dispensary had thus been enabled to keep on in a locality where there were two general hospitals, besides free dispensaries.

Mr. J. HOGG hoped that Mr. Kemp would convert his dispensary into a provident dispensary. Many persons would rather join provident dispensaries than attend the out-patient department of hospitals. This was the opinion of the supporters of the Hospital Saturday Fund, who had devoted a portion of the fund to provident dispensaries. He would remind Mr. Holmes that many of Messrs. Spottiswoode's workmen had also given evidence in favour of the provident dispensary system.

A VISITOR remarked that one objection against provident dispensaries was, that good cases were required in hospitals for the purposes of instruction; and the medical officers of the dispensaries would be anxious to retain such cases and treat them themselves. If this were so, it was a great difficulty.

Mr. W. RIDGEN said that the out-patient departments of hospitals might at once be suppressed where there were no medical schools; where there were schools, the severe cases were taken into the hospital as in-patients. He thought that the out-patient departments might be converted into provident dispensaries under the control of the physicians, physicians' assistants, etc.; and that many of the patients might be visited at their homes by the students, in the same way as was done in the midwifery departments of the hospitals. He had lately endeavoured to form a provident dispensary in Brompton, and had applied to the authorities of St. George's Hospital to ascertain if they would take in-patients sent from the dispensary: but they had declined to do so.

After some remarks from Dr. GRIGG, the discussion was adjourned to Wednesday, March 27th.

#### LANCASHIRE AND CHESHIRE BRANCH: INTER-MEDIATE MEETING.

THE first intermediate meeting of the Lancashire and Cheshire Branch was held at the Town Hall, Oldham, on Tuesday, March 5th. In the absence of the President (Dr. Steele), Dr. ROGERS, one of the Vice-Presidents, occupied the chair. Eighty-five members were present.

*Address.*—Dr. BROADBENT (London) gave an address on the Mechanism of Speech and Thought as illustrated by Pathology.

*Communications.*—The following communications were made.

1. Dr. J. G. ROBERTSON read the history of a case of Multiple Mammary Tumours.

2. Dr. LLOYD ROBERTS showed specimens of Distorted Pelves.

3. Dr. SINCLAIR showed an Infant suffering from Bell's Palsy.

4. Dr. PATTERSON exhibited Injected Microscopic Sections of the Liver, Kidney, and Spleen from a recent case of Amyloid Disease.

5. Dr. HUMPHRIES read a paper on Scarlatinal Nephritis, and showed specimens illustrating its pathology.

6. Dr. LEECH and Mr. CULLINGWORTH showed three cases of Pseudo-hypertrophic Paralysis.

7. Mr. JONES showed a specimen of Necrosis of the Femur following Suppurative Periostitis.

8. Dr. DRESCHFELD and Dr. ROSS exhibited, by means of the Oxy-hydrogen light, Microscopic Sections illustrative of Diseases of the Spinal Cord.

*Exhibitions.*—Some of the newer forms of instruments used in medicine and surgery were exhibited by Messrs. Wood, Holderness, Arnold and Sons, and Salt; Messrs. Harvey and Reynolds, Ferris, and Wooley showed new drugs and pharmaceutical preparations; Messrs. Mottershead and Co. showed their batteries and electrical appliances.

*Dinner.*—After the meeting, forty of the members dined together at the Angel Hotel.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 12TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

AN ACCOUNT OF FIVE HUNDRED CASES OF OPERATION FOR STONE IN THE BLADDER OF THE MALE ADULT, WITH REMARKS ON THE MOST IMPORTANT INCIDENTS WHICH HAVE OCCURRED IN CONNECTION WITH THEM.

BY SIR HENRY THOMPSON, F.R.C.S.

THE 500 cases were in adult males, that is, of twenty years old and upwards, the great majority being from fifty to seventy years. The mean age was sixty-one years and a-half. They comprised Sir H. Thompson's entire and unselected work from the first case up to January 1877. The published experience of Cheselden, Martineau, Brodie, and Fergusson was recorded. The sum of similar cases treated by them was 422. Of these 422, 69 were fatal, or 16½ per cent., i.e., 1 in rather more than 6 cases. Of the 500 in question, 422 were by lithotrity, and 78 by lithotomy. The number of individuals operated upon was 420. Several of the lithotrity patients being operated upon twice, a few three times. In all cases, a considerable interval and evidence of fresh formation, mostly a newly descended uric acid calculus, had existed. Small phosphatic concretions, although removed by lithotrity, were not reckoned as stone in the bladder. The chemical constitution of the calculi was as follows: uric acid, 313; phosphatic, 99; mixed, 81; cystic oxide, 1; pure phosphate and carbonate of lime, 2; phosphatic calculi formed on foreign bodies, 4. The mortality, accepting almost any death occurring within six weeks of the operation, was as follows: in 422 cases of lithotrity, 32 deaths, or 1 in 13 cases; in 78 cases of lithotomy, 29 deaths, or 1 in 2½ cases; in the total 500, 61 deaths, or 1 death in 8½ cases. The causes of death which were given in each case were tabulated, compared, and contrasted in the two operations, with inferences thereupon. Accidents met with in operating by each mode were detailed, and the manner in which they were dealt with. The general inference was arrived at that it is unwise to apply, as a rule, lithotrity to any stones above moderate size; and, if any calculus be sufficiently large to require what is known as the fenestrated instrument, it is better to employ lithotomy. The author had not employed such an instrument during the last ten years. Finally, remarks were made on the after-history of patients who had been operated on by lithotrity.

The PRESIDENT, in returning the thanks of the Society to Sir Henry Thompson for his paper, complimented him on the clearness with which he had expressed his views.

Mr. CADGE said that the paper was important in more than one respect. That one surgeon should have operated on 500 cases of stone in twenty years showed the growth and development of specialities and division of labour in the profession. It also showed the successful results obtained. The object was not to discuss the methods of proceeding, but rather to examine statistics and determine the relative value of lithotomy and lithotrity. He admitted that statistics were liable to fallacy; but still an endeavour might be made to ascertain the rate of mortality after the operations. Sir H. Thompson had had 422 cases of lithotrity, with 32, or including three doubtful cases, 35 deaths—a mortality of about 8 per cent. But, on putting together the statistics of Sir W. Fergusson, Sir H. Thompson, Mr. Liston, Dr. Keith, and himself, he found 892 cases, with 74 deaths; still showing a death-rate of about 8 per cent. As to lithotomy, he would like to know the mortality in the patients above fifty years of age. Taking the cases operated on by Crosse of Norwich, before the introduction of lithotrity, he found that the average age was sixty years and the mortality 41 per cent. If, then, the death-rate after lithotomy above fifty years was 30 per cent., and if that of lithotrity was 8 per cent., this indicated the great superiority of lithotrity over lithotomy as regarded immediate danger to life. But this statement was subject to the qualification that the size and weight of the stone must be taken into account; and these were greater in lithotomy than in lithotrity. His own experience in Norwich had been very similar in many particulars to that of Sir H. Thompson. He hesitated to compare it with the practice described in the paper, as it amounted to but 220 cases; viz., 134 of lithotomy and 86 of lithotrity. Of the lithotomy cases, 104 were in adults. An important point was the after-history of the cases, as to the recurrence of stone. In Crosse's tables of 700 cases of lithotomy, there were only 12 of recurrence; and in most of these the return was due to fragments of stone having been left in the bladder. He had himself seen but few

cases of recurrence. After lithotrity, recurrence was not uncommon, and the fact must be accepted as a drawback on the operation. Another point to be borne in mind with regard to lithotrity, was the liability to cystitis and phosphatic deposit after the operation. This, which had been alluded to by Sir H. Thompson as one of the penalties which must be paid for lithotrity, had been ascribed partly to the irritation of sharp fragments of stone and partly to retention of urine. He admitted these causes; but he thought that a more frequent one was sacculation of the bladder, depending on enlargement of the prostate and impediment to the outflow of urine. In a large proportion of cases of chronic enlargement of the prostate, the bladder was more or less honeycombed or sacculated. Supposing that in such a case a calculus in the bladder were crushed, some of the fragments might readily be deposited in the sacculi, and either set up acute inflammation, or lead to chronic cystitis, with phosphatic deposit. This was no doubt the explanation of many cases of cystitis, with phosphatic deposit, in old persons. He believed that, in most of the cases of recurrence after lithotrity, the stone was formed in the bladder on the fragments which had been left; and this was not to be wondered at when the difficulty of removing the fragments was considered. He thought that the greater liability to return of calculus after lithotrity went far to balance the advantages of the operation. He would, however, say that every year's additional experience proved that lithotrity, when judiciously applied, was capable of saving many lives, and was an enormous boon to suffering humanity.

Mr. W. D. NAPIER called attention to the importance of detecting the existence of stone in the bladder soon after its descent from the kidney.

Mr. J. F. WEST said that the surgeons in Birmingham and the neighbourhood saw a good deal of stone. He had collected the statistics of cases in and near Birmingham, amounting to 108 cases in three years, most of them being in children. In 81 operations for lithotomy, of which the results were known, there were 74 cures and 7 deaths. More cases of stone were met with in the hospital at Wolverhampton than in any other in the district. From December 1859 to 1876, there were 134 cases of lithotomy, with a mortality of 1 in 12.18. In patients under forty years of age, the death-rate was 1 in 16.81; in those above forty, it was 1 in 5. He thought that the greater proportion of cases of lithotomy among children, in the Midland district, was to be accounted for by the fact that a large number of the adults went to London in order to be operated on. In the Midland district, many surgeons preferred the median operation, having been led to practise it by Mr. Allarton. Mr. West thought it suitable for children, but not for adults, nor for cases where the stone was large.

Mr. MACNAMARA had passed much time in the North-Western Provinces of India, where stone was very common, and very large calculi were met with. He would not enter on statistics, as the circumstances of the cases in India were very different from those in England. He had almost always treated his cases by lithotomy, and was glad to hear that Sir H. Thompson was disposed to go back to that operation in many cases. At first, he had followed the precept of Sir W. Fergusson and other surgeons, that the incision should be small; but he afterwards found that success depended to a great extent on making a free incision. Much mischief was done by the tearing of the parts; and, in cases of large calculus, he had obviated this by first breaking up the stone, and then removing the fragments by lithotomy. Another important point was the preparation of the patients for operation, which, he thought, was not sufficiently attended to. It was impossible to do lithotomy successfully without two or three weeks' careful preparation.

Sir JOSEPH FAYRER called attention to a work by a native hospital surgeon (Baboo Ram Narain Dass), who had had 248 cases of lithotomy in the North-Western Provinces, with 17 deaths. The operation there was much more successful than in Bengal. He was glad to hear Sir H. Thompson's remarks about reverting to the old operation.

Sir JAMES PAGET said that such papers as that of Sir Henry Thompson were calculated to make one look on surgery as a very happy profession, as it was capable of relieving so much misery. The present, however, might be a fair time for reconsidering the question of the comparative advantages of lithotomy and lithotrity. His own experience had been less than that of Sir H. Thompson, but he must confess to a growing preference for lithotomy. He thought that Sir Henry Thompson's experience showed that the best attainable results of lithotrity had been arrived at, at least for some time to come. But much improvement in the method of treating patients after lithotomy might be expected. Even without the adoption of the antiseptic treatment—which obviously was not applicable—there was great improvement in the results of the operation. Peritonitis and urinary infiltration were now rare; and greater care was taken than formerly not to operate on patients who were in an unfit condition. He believed that, if a fresh

start were taken in lithotomy, the mortality would be nearly as low after it as after lithotripsy.

Mr. TEEVAN believed that the condition of the patient after lithotomy was a most important matter. He had performed lithotomy forty-two times in eighty-seven cases of calculus. Lithotomy would sometimes fail most lamentably; but this was no bar to the operation. He had seen five cases in which there had been a recurrence of calculus after lithotomy after intervals of several years. What was to be done with the cases of lithotomy which were neither killed nor cured? In a case of chronic cystitis following lithotomy, he had followed the plan recommended by Dr. Gouley of New York, and had performed urethral section; the patient recovered, and continued well.

Mr. LUND had given much attention to the antiseptic treatment of wounds. The rare occurrence of septicity after lithotomy was a very good example of the results of irrigation. The lithotomy wound was irrigated by a peculiar fluid, the urine; which consisted not only of water, but contained saline matters in solution. The urine flowing over the wound constantly removed the morbid products, and sloughing was very rare.

Mr. HOLMES suggested that the urine which flowed over the wound contained bacteria. He thought that the success was to be explained by the constant drainage.

Dr. BROADBENT thought that an accumulation of morbid material was almost impossible in lithotomy wounds.

Mr. SPENCER WELLS said that in Sir H. Thompson's cases there was apparently a large number of cases of cystitis. This was probably to a great extent due to the decomposition of the urine by the introduction of germs or elements of septicity with the lithotrite or catheter. This should be prevented by the use of carbolic acid or thymol or something of the kind. It had been stated by Sir H. Thompson that wound of bladder could scarcely occur. He remembered a case in which the late Mr. Tyrrell, at St. Bartholomew's Hospital, wounded the back part of the bladder in performing lithotomy; and Mr. Tyrrell hence recommended that the knife used should be short.

Mr. WALTER COULSON referred to some accidents attending lithotomy. He had seen a case where the instrument could not be withdrawn, and it was necessary to make an incision in the perineum. In another case, the screw had broken down, and the male blade of the instrument had cut into the urethra, being released with difficulty only by a series of sharp concussions. In another case, the withdrawal of the instrument was impeded by the lodgment of a fragment of stone between the blades.

Mr. T. SMITH said that, if the lithotrite became clogged with a stone, it could be freed by means of the finger introduced into the rectum.

Mr. MAUNDER congratulated the author of the paper; but doubted whether it was advantageous, as regarded the education of the profession, that so large a proportion of cases of operation for stone should go into the hands of one surgeon.

Sir HENRY THOMPSON thanked the meeting for the manner in which his paper had been received; and especially those members who had come from a distance to take part in the discussion. He thought that lithotomy and lithotripsy were often contrasted from a wrong point of view. They were not at all antagonistic, but rather complementary of each other. In but few cases could there be a dispute as to which should be done. He thought all surgeons agreed—a lithotomy which could remove the stone at two sittings was the best operation; and many calculi came into the category. In reply to Mr. Napier, he said that stone in the bladder could be detected at an early stage by any intelligent medical man. The profession was not altogether to blame for the failure to detect stone in the early stage; the explanation lay, to a great extent, in the reluctance of many patients to believe that they had stone. As to the cases of diseased bladder met with after lithotomy, he would say that, if such cases were more rare after lithotomy, it was because they died after the operation. He was not reverting to lithotomy; but he would, perhaps, do it now in some of the cases in which he formerly performed lithotripsy. The accidents attending lithotomy were generally due to attempts to crush too large a stone. He agreed with Mr. Spencer Wells as to the value of disinfection of the instruments by antiseptic solutions.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 8TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Unilateral Atrophy, with Muscular Spasm (Athetosis).*—Dr. F. TAYLOR exhibited a woman aged 22, a needlewoman, who had been for some years affected with violent tonic spasms of the muscles of the left arm and leg. The exact date of the commencement of the disease

was uncertain; but it was probably in the later period of childhood. She then had some kind of febrile disorder, and during convalescence first noticed twitchings in the left biceps muscle. She suffered no inconvenience for some little time, but it gradually developed to its present condition. The muscles of the arm and shoulder on the left side were greatly hypertrophied, but the limb itself was shorter than its fellow, while the left side of the chest was also smaller than the right side. Sitting or standing, she commonly held the left arm firmly to the side, the left fingers often grasping the other hand tightly. Any attempt to move the hand or arm was accompanied by violent contractions of the muscles of the whole arm, but of the extensors chiefly, so that the arm was fixed in a straight position; but the fingers were partly flexed, partly straightened. This extension was not brought about suddenly, but quite slowly and deliberately. The spasm continued as long as the arm remained extended. If, however, she attempted to flex the arm, the extensor muscles shortly relaxed, she brought the elbow to a right angle, and all the contractions subsided. The toes were drawn down towards the sole of the foot by a similar condition of the muscles of the posterior tibial region; and walking was in consequence very painful to her. The contractions themselves caused her much pain, constantly recurring, apparently spontaneously, and frequently woke her during the night. The muscles of the affected side responded to galvanism and faradisation, but required somewhat stronger currents than the healthy muscles. There was no anaesthesia. She had obtained some relief from the spasms under bromide of potassium and the application of the continuous current. Dr. Taylor said there was no doubt unilateral atrophy, which was probably due to a cerebral lesion, in early life, interfering with function, and so retarding growth. The more interesting question was as to the nature and connections of the spasmodic movements. Comparing them with those noticed by Dr. Hammond in his cases of athetosis, Dr. Taylor observed that the spontaneous irregular movements of the fingers described in Dr. Hammond's first case were not present here; but that between the second case of athetosis and the present one there was a sufficiently close resemblance. If not admissible as a case of athetosis, it would have to be included under the wider head of spastic contracture.

The PRESIDENT asked if the spasm was *bond fide*.—Dr. TAYLOR thought so, especially having in mind a reference to a similar condition seen in young children, of which a case was recorded by Dr. Gowers.—Mr. BARWELL questioned whether the left side was atrophied, for, if there were hypertrophy, this might give rise to shortening. It was rare to see spasm and hypertrophy associated in young persons; generally there was wasting.—Mr. HULKE objected to the use of the word "contracture" as employed by Mr. Barwell. He thought it should be applied to permanent contraction without the possibility of extension.—Mr. BARWELL explained that it was in this sense he employed it.

*Large Aneurism of the Left Subclavian and Axillary Artery treated by Rest and a very restricted Diet.*—Mr. HULKE read the notes of this case. A French-polisher, aged 36, but much older in appearance, addicted to drink, after suffering from pains in the left shoulder and arm, supposed to be rheumatic, during two months, became aware of a swelling at the root of his neck on the left side, for which he went into King's College Hospital. Dissatisfied with what was there done for him, he left this hospital; and five months after the beginning of his illness entered the Middlesex Hospital, 28th March, 1877. At this time, he had a large aneurismal tumour filling the axilla, and implicating also the third, second, and presumably, to some extent, also the first part of the left subclavian artery; and he suffered great pain down the arm and over the shoulder-blade. He was kept in bed, and enjoined to keep perfectly still—not even to sit up or to move off the bed for any purpose—and he was put on a very limited non-stimulating diet. This was followed by rapid mitigation of the pain, by decrease of the aneurism, and its obstruction by clot. He was discharged for disorderly conduct in June, at which time the axillary portion of the sac had shrunk to the size of an acorn, and was quite impervious; and the cervical part was very small, and it felt very firm. It was thought that a slight pulsation of this part might be communicated. He afterwards entered Charing Cross Hospital, where, Mr. Hulke learned, doubts were entertained of the nature of the affection. This Mr. Hulke took to be confirmatory of the permanence of the consolidation and occurrence of a cure. The encouragement the case afforded for the trial of a modified Valsalva's method in aneurism, where the ordinary direct surgical methods were not applicable, induced Mr. Hulke to submit the case to the consideration of the Society.

The PRESIDENT said the great difficulty in these cases was to get the patient to submit to the treatment for a long enough period, and referred to the case of a woman who had been under his care, but who, after receiving a certain measure of relief, refused to submit any longer, and left the hospital. Still, he thought the plan a very good one. It

had been tried in popliteal aneurism, but he had never employed it himself. He had, however, found other methods useful, inasmuch that he had only once tied an artery for aneurism.—Mr. BARWELL said the case referred to was under the nominal care of his colleague Mr. Canton; and, when in Charing Cross Hospital, there was a solid doughy tumour rising above the clavicle, uneven on the surface, and not pulsating except in transverse lines in the direction of certain superficial vessels. The patient left the hospital; after a time, he returned, the tumour being then decidedly larger; finally, he had to be got rid of, and was lost sight of. He thought the tumour glandular or malignant, though there may have been an aneurism beneath it at one time.—Mr. GANT mentioned a case of subclavian aneurism which had been treated in various ways: by restricted diet, by bandaging, and by distal compression; but nothing did good. Finally, the vessel was tied on the cardiac side; but death resulted from secondary hæmorrhage.—Dr. SILVER said he had seen the case referred to in Mr. Hulke's paper whilst the patient was in Charing Cross Hospital. At the time when he saw it, and without the history subsequently obtained, it could not have been called an aneurism. It was quite solid, and did not pulsate except in a transverse line, as indicated by Mr. Barwell. There was, however, deep-seated dulness in the upper part of the chest, extending downwards to about the level of the third rib in front, and reaching to the back of the chest. He thought that the case referred to by the President had also been at one time under his care. At all events, a woman having an aneurism similar to that described had been treated in the way mentioned by the President. After improving, she refused to submit any longer to the treatment, and subsequently became an inmate of St. Bartholomew's Hospital, stating that she had been dismissed as incurable, whereas she left of her own accord, being of that class of patients who will not submit to treatment after a measure of relief is obtained.—Mr. WARRINGTON HAWARD mentioned a case of carotid aneurism, where, for various reasons, operation was undesirable, treated by restricted diet. There was no great difficulty in getting the patient to keep to a limited diet, though some persons could not stand it. There was no solidification, but the tumour did not pulsate so much. As soon, however, as ordinary diet and habits were resumed, there was a tendency for the pulsation to increase. He referred also to the case of a medical man, who carried out the treatment carefully. His greatest difficulty was the want of fluid. The pulsation of the aneurism diminished, but apparently no clot formed. The improvement seemed to depend on the rest alone; it soon disappeared on motion. Ultimately, death ensued.—Dr. POWELL asked whether any sphygmographic tracings had been obtained; they would have been useful in the diagnosis. He remarked on Mr. Hulke's plan of limiting the food but not the fluid; he thought it much more important to limit the fluid. The food, too, should be nitrogenous, as we must look for a permanent cure, and not to the mere formation of a clot. The deposit should be distinctly stratified. He had now under his care a case of aneurism of the aorta, which he was treating with a free animal diet, but restricted fluid.—Mr. MAUNDER said it was somewhat venturesome for anyone who had not seen the patient whose case had just been related, to express an opinion on the nature of the swelling. Personally, he accepted Mr. Hulke's view—that it was aneurismal—and did not deem it necessary to think, with Mr. Barwell, that, while there had been possibly an aneurism, the existing tumour was malignant, simply because, while the growth persisted, there was an absence of pulsation and of *bruit*. He had two cases in his mind's eye of very large swellings of the popliteal region, in which (the history being unreliable) it was impossible to determine between aneurism and malignant disease. Amputation disclosed ruptured aneurism, the explanation being extravasation and coagulation of blood, which, being no longer circumscribed by the sac, ceased to pulsate.—Dr. MAHOMED did not think the sphygmographic tracings would be of much use in such a case. The plan of getting a simultaneous tracing of the heart and of the pulse, as invented by Dr. Burdon-Sanderson, might be useful.—Dr. BARCLAY referred to a case of aneurism completely cured. The condition was supposed to be malignant at St. Bartholomew's. Ultimately, the man died of phthisis in St. George's Hospital. Almost the whole of the right side of the chest was filled with an old clot. The other lung was riddled with vomicae. In another case, he had tried full diet, but restricted the amount of fluid. The patient did well, but had difficulty in digesting his food.—Dr. IRVINE asked what benefits had been seen from the use of iodide of potassium. He had seen much benefit, and referred to the case of a carpenter who was doing fairly well under its use, though continuing his trade. He had now been under notice for twelve months, and the iodide never failed to relieve any bad attack. He had seen marked advantage, too, in other cases.—Mr. MORRANT BAKER had seen a case where, as in this, there might have been a gradual leakage, and a gradually increasing clot which did not pulsate. The patient in

this case died from rupture into the pleura.—Dr. ANDREWS believed Tufnell's to be the best plan of treating these internal aneurisms. All had seen cases improving or stationary, but, except by this method, we never saw a complete cure. He had seen several. This was not so in all cases; in some there was even some risk in its use. Especially mental strength and vigour were required in the patients. He had seen two die: one from rupture, one (an old man) from an insidious pneumonia. The food should be scanty, but nutritious; the fluid limited. Patients submitted to it best if put on it at once.—Mr. HULKE was well pleased with the individual experience his paper had elicited, and the subsequent history was valuable. As to the diagnosis, he was quite certain of it. Sphygmographic tracings had been taken, but they could not be found. He did not limit the water from experience, but rather adopted Todd's plan. The remarks of both Mr. Maunder and Mr. Baker were apposite. The idea had crossed his own mind, but he was not certain. There was, however, no ecchymosis, and he had seen that in all cases of aneurism pulsation may continue after rupture. The iodide was not satisfactory.—The PRESIDENT suggested the benefit of freezing a portion of the water allowed as food.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MARCH 5TH, 1878.

CHARLES MURCHISON, M.D., D.C.L., F.R.S., President, in the Chair.

ON taking the chair, the PRESIDENT reminded the members of the Society that the next meeting would be devoted to specimens connected with Diseases of the Lymphatic System.

*Dilatation of Heart and Aorta from old Spinal Disease.*—Dr. GOODHART exhibited such a specimen from a girl aged 7, who had old-standing disease in the lower dorsal vertebrae. The abscess was opened, but the child sank. At the *post mortem* examination, the heart was found globular and full of *ante mortem* coagula. The left ventricle was dilated. The aorta was folded up at the seat of the vertebral disease, in such a manner as must have greatly obstructed the flow of blood. There was amyloid disease of the other viscera, and advanced renal disease. In a similar case, even acute endocarditis had been found. The folds projected into the canal of the aorta.—In answer to a question put by Dr. DOUGLAS POWELL, Dr. GOODHART said there was no atheroma—the aorta was somewhat thickened; and to a question by the PRESIDENT, he said that there was no evidence of anything wrong with the heart in life.

*Lymph-Scrotum.*—Mr. G. C. COLES stated that this condition of the scrotum was due to a varicose condition of the scrotal lymphatics. It was apt to occur after ague. The glands enlarged, even to the size of hen's eggs. The skin became corrugated, and, if pricked, a milky fluid flowed out. Then an elephantoid state was established. Filariæ were found in the blood. They did not adhere to the blood-corpuscles. They were from an hundredth of an inch in length to one-three-thousandth in thickness.—Mr. MORRANT BAKER inquired as to the colour of the fluid which exuded.—Mr. COLES replied that it was milky.—Sir JOSEPH FAYRER said that this condition was first described by Dr. Vandyke Carter in 1861; and that, not knowing this, he described it in 1865 as *naevoid elephantiasis*, stating that it was due to nematoid worms. He believed that other forms of malarial and cachectic disease found in the tropics would be found to be due to such entozoa. As to the fluid which exuded at first, it was pale and white, with a specific gravity of 1020, coagulating firmly. Then it became of a pink shade, or even might assume a blood-like hue. In answer to a question put by the President as to the presence of filariæ in non-naevoid conditions, he said that, so far as he knew, they had not yet been found.—Dr. SPENCER COBBOLD referred to the larval condition of the worm. He then gave an interesting account of the discovery of these worms. Bancroft first found the sexually immature forms of the worm, and could diagnose certain forms of disease due to filariæ in passing through a hospital-ward. Mosquitoes get filariæ when sucking human blood. Dr. Manson of Amoy had observed all forms up to the sexually perfect. He found no fewer than one hundred and twenty filariæ in the stomach of a mosquito who had fed on a man affected with filariæ, who had been deliberately placed in a room for the purpose of giving these filariæ to the mosquitoes in it. The female mosquito, when gorged with blood, goes to the water to deposit her eggs, and thus the filariæ find their way into water, and so back again to man.—The PRESIDENT said he thought the lymph-scrotum should be submitted to the Morbid Growths Committee.—Dr. CROCKER said the blood of a patient with elephantiasis of the leg had been examined, and no filariæ were found. The patient had never been out of England.—Mr. COLES said a low power only must be used to find the filariæ.

*Worms in Heart and Oesophagus of a Dog.*—Mr. COLES exhibited these worms. Such entozoa were very common in China; and it was estimated that fifteen per cent. of the natives of Amoy were possessed of them. Five different species had been found in dogs, both tenia and filaria. An unusual exertion on the part of dogs was apt to prove fatal. On *post mortem* examination, worms were found in the heart and vessels, each worm being surrounded with a dark mass consisting of its young. The males were smaller than the females; some of the worms were five inches in length. These worms were filariae, and the mass might press upon and obstruct the oesophagus. In one case, a tuft of them burst into the pleura, setting up pleurisy. In one case, paralysis of the hind legs was due to plugging of the spinal capillaries. Their ova were found in the intestines and viscera.—Dr. COBBOLD said those worms were first observed in Paris in 1812. They were always found on the right side of the heart. They were not so harmless as they seemed. Dogs died in great suffering from the filaria immitis.

*A Rare Form of Psoriasis.*—Mr. BALMANNO SQUIRE exhibited a drawing of a rare form of psoriasis. It occurred as a congenital port-wine mark in a man aged 42, and the psoriasis had existed nine years. Psoriasis, he said, rarely attacked the forehead. In this case, the scales extended into the hair, and also down to the eyebrows; while the eyelashes were affected. On the forehead, the scales of more recent growth were seen to be very white. When the skin was stretched, fissures formed.

*Nævus complicated with Molluscum.*—Mr. BALMANNO SQUIRE sent round a drawing illustrating this complication.

*Disease of the Spinal Cord in Diabetes.*—Dr. SILVER gave an account of the clinical history of a case of diabetes. The patient was a man aged 19, who had been ill for some time with diabetes. He was emaciated; his skin was harsh and dry; and his tongue dry and furred. He suffered from thirst and great voraciousness. The amount of sugar in the urine was not remarkable. The temperature-chart was very interesting. It took a sudden rise from 97 deg., and then fell to 95 deg. This occurred several times. Then the temperature rose to 104 deg., and the youth died. There were no indications in life of the changes found after death. These changes had a bearing on the origin of diabetes, and corroborated the nervous theory. He then described the fibres known to pass down from the vertebral arteries into the lower cervical ganglion, and thence down the ganglia of the sympathetic, and onwards by the splanchnics ultimately to the liver (the fibres described by Cyon and Aladoff). He said other fibres took another route issuing further down at the first or second dorsal vertebrae, and thence getting to the sympathetic ganglia. A large cavity was found in the apex of a lung, which was not true pulmonary phthisis, but a necrotic cavity. There was no odour produced thereby. There was nothing to be found in the floor of the fourth ventricle. No examination with the ophthalmoscope had been made in life.—Dr. PEARSON IRVINE described the *post mortem* appearances met with in Dr. Silver's case. The necropsy was made thirty-six hours after death, and the body was found rigid. The spinal cord was first examined, and the tissues outside the sheath were generally hyperæmic. Opposite the third, fourth, and fifth dorsal vertebrae on the left side was a clot undergoing some change, about three inches long, quite outside the sheath of the cord. In the lumbar region were found along the whole length peculiar jelly-like masses of bright pink colour, which, on examination, was found to be connective tissue infiltrated with bloody serum, which had coagulated within it. On slitting open the sheath, distinct extensive softening of the substance of the cord was found opposite the fourth and fifth cervical and the first, second, and third dorsal vertebrae, where the cord was almost diffused, all parts below being firm in consistence. Exactly opposite where the clot mentioned was found, there was a beautiful pink injection of the vessels of the pia mater. The vessels formed an exceedingly fine network. Three inches of the cord from the last dorsal vertebra down to where the cord begins to split up presented exactly similar appearances. Considerable quantities of serum escaped when the lumbar region was opened. There was no change in the medulla oblongata; the floor of the fourth ventricle was healthy. The brain, especially on the left side, was hyperæmic, and the left island of Reil was partly softened, the softened parts cracking away, and being distinctly pathological. On the pericardium was a mass of tissue like that at the lower end of the spinal canal, and like masses were found round the base of the heart and surrounding the kidneys. The heart was small, but otherwise healthy. The upper lobe of the right lung was converted into a cavity, the walls of which were rugged, and indicated a rapidly destructive process. The cavity was filled with grumous reddish fluid and solid contents—the debris of lung-tissue and disintegrated blood. The middle lobe was solid, and in an advanced stage of pneumonia. The apex of the left lung contained caseous nodules, and other parts of both lungs were emphysematous. The liver was

large for the size of the body, and was hard, firm, and of an uniform dark red colour. The kidneys were hypertrophied, and the pancreas very small and hard, as if from contraction.

*Hypertrophic Lupus.*—Mr. SANGSTER described a case which occurred in a man aged 24, who was healthy looking. He had had this sore since fourteen years of age. When first noticed, it was of the size of a florin. It did not occasion much pain. It was situated in the tuberosity of the right ischium. It was about four inches in diameter, and extended to the fold of the buttock. It was hard to the touch, and its surface was polished with some scarring. At its margin was a fringe of livid red tubercles, mostly where the left buttock overlapped it. On the hypothesis that it might be of specific origin, it was treated accordingly, without effect. It was then excised, and found to be attached to the fascia of the glutei muscles. The case did well. One section showed the first stage of cells around the vessels; a second, the tubercles where the Malpighian layer was hypertrophied; and in a third, from the cicatrising part, fibrous tissues were found around lymphoid cells; a fourth section showed a giant-cell.

*Renal Calculus containing Indigo.*—Dr. ORD described a calculus containing indigo. Indigo was sometimes found in normal urine; indican existed in all urine. No indigo had ever hitherto been discovered in a calculus. This stone contained a large quantity of indigo blue. He had the calculus and the kidneys sent him. The calculus was a mass like a lozenge in the pelvis of the right kidney. The kidneys were diseased, and the right one was suppurating. The calculus was brown in the interior, crusted over with blue-black material. When a portion was burnt on platinum-foil, it gave out a sooty smoke like burning indigo. It burnt nearly completely, the ash being chiefly phosphate of lime. Under the microscope, the brown part was seen to be a crystalline mass of a blue colour, which was not blood-pigment. When dissolved in hydrochloric acid, there was a black residue, with blue characters. Was this indigo? If a small part were put dry into a test-tube and heated to a degree below redness, a bulky vapour was produced like iodine vapour; and, when the heat was removed, this crystallised in six-sided tablets like indigo. When looked at through the spectroscope, the spectrum agreed with that of indigo; the yellow band being hid by a darker band. The question was, how was it formed? There was nothing in the diet or in the medicine, though creasote had been given freely to check the vomiting. Dr. ORD then spoke of indogen and of indol. Indigo in the urine might be connected with anything hindering the passage of fæces down the small intestines. It was also found in the urine of cholera patients. It was found, too, in chronic suppurating, especially when connected with the urinary tracts. He thought the indigo colouring matter was deposited on a nucleus in the suppurating kidney.—The PRESIDENT said that the calculus certainly contained indigo.—Dr. THUDICHUM said it was a remarkable discovery. The material crystallised and vapourised like indigo; it behaved chemically like indigo; and gave an identical spectrum with indigo.

## CORRESPONDENCE.

### THE REPORT OF PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

SIR,—The letters of Dr. Falconer and Dr. Stewart make certain statements before my fellow-members which render it necessary that I should reply to them.

As regards my former communications, I think it requisite to point out that my observations apply in part only to the nature of the Proceedings of the Committee of Council, and in part to the nature of the official document published in the JOURNAL, purporting to be a "Report of the Proceedings of the Committee of Council". My object has been to call attention to the fact, that what was officially furnished to the JOURNAL for the information of members a month after the meeting, as a "Report of the Proceedings" at the meeting of the Committee of Council of January 9th, was neither an intelligible document nor an adequate account even of those parts of the proceedings which it intended to report; that, in respect to subjects which it noticed, it left out some parts, highly interesting to the members of the Association, of the proceedings on their behalf of their representatives on the Committee of Council; besides omitting others, by their nature and by their operation essentially interesting to the members, and affecting the general interests of the Association. Thus, for example, while it was stated that a house was leased in the Strand at a rent of £320 a year, there was no notice that a sum of £1000 was to be spent on repairs, etc., and that further large sums would be required for fittings and printers' plant. Again, the resolution in reply to Dr. Wilson Fox's

letter was mentioned, whilst an amendment duly moved and seconded was omitted. Finally, whereas a series of important regulations were adopted, including one which regulates the practice hitherto prevailing and the privileges of members in proposing resolutions at the Annual Meeting, no mention whatever was made of such regulations in the published report.

My objection to this report as published is, that it is not drawn up so as to afford an intelligible or adequate account of the proceedings of which it is described by its heading as being a report. It seems to me that the object of such official reports, if they are to be of any service, is to give to the members as full an account as is consistent with the conduct of business, in order that they may, in the intervals of the annual meetings, be conversant with the more important proceedings of their executive representatives, especially with regard to such matters as are intended to be brought before the Annual Meeting, and on which legislation is to be proposed, so that they may be able to exchange and develop opinions, and take mutual counsel on the subject in the JOURNAL or in the Branches. The several subjects discussed at the late meeting of the Committee of Council included some on which it seemed to me that opportunity should be afforded for common counsel and leisurely suggestion; notably as to—1. The present position of the Association in respect to women actually being or proposing to become members of the Association; 2. The decision to lease and fit up, at a large expense, premises intended to combine and locate in a costly business thoroughfare the central committee-room and offices of the Association over a printing and publishing office and shop; and the intention to undertake the business of printers; 3. The proposals for the improved and altered conduct of the annual meetings. The sooner important resolutions adopted are made known to the members, the better their chance of discussing them and of making known their views in relation to such proposals before they become accomplished facts.

Dr. Falconer states "that no secret whatever has been made of the intentions of the Committee of Council to acquire premises for the publication of the JOURNAL". In the Report of Proceedings of the meeting on October 10th, 1877, published in the JOURNAL of November 24th, there is no reference to the acquisition of premises. In the report of the meeting of January 9th, the acquisition of premises is published as an accomplished fact. I have only to add, on the subject of secrecy—1. That the minutes of the Committee of Council are forwarded with the mark "Strictly Private and Confidential". This seal of secrecy is never taken off. 2. That the members of the Committee of Council are prohibited (as I have been) from communicating the minutes even to the Councils of the Branches of which they may happen to be the official delegates. 3. That although the most important business is included in the minutes of subcommittees brought up and adopted, these are wholly omitted in the published reports.

Dr. Falconer and Dr. A. P. Stewart reproach me with having been absent from a meeting of the Committee of Council on the 10th of October, when the premises were discussed and viewed. I have only to say, that the General Secretary failed to send me a summons to attend any such meeting of the Committee, and I was quite unaware of the meeting or its objects. In fact, it was not until about the end of October, owing to this failure of the Secretary, that I discovered I had a seat in the Committee of Council. The published report, as I have said, does not even mention the subject of premises.

Dr. Stewart's remark that I now tantalise the Association with the mention of a wonderful bargain, which I ought to have brought under their notice earlier, is groundless. I only became aware of the proposed expenditure on premises in the Strand after the January meeting. I went into the Strand and looked at them, and saw, at the same time, the cheaper premises requiring no capital outlay, to which I refer. I proposed at once to bring the subject under the notice of the Council of the Branch which I represent on the Committee of Council; but Mr. Fowke, to whom I communicated that intention, immediately wrote to state that the minutes of the Committee of Council are "strictly private and confidential", and that I therefore had no power to communicate them to the Branch. I waited a month for the appearance of the report in the JOURNAL; when at last it appeared, it omitted, as it seemed to me, the most important points. It was then that I wrote to the JOURNAL, asking that further information as to the facts and a more adequate account of the actual proceedings might be given to the members of the Association and of the Branches, in order that they might review and consider them.

Had a more adequate Report of the Proceedings of Committee of Council in October last been issued, these objects would have been achieved, and the members of the Association could have discussed the proposals of the Committee before the seal of the Association was affixed to the lease. When I asked that a fuller report of the January proceedings might be forthwith published, I supposed that no objec-

tion would be made, as I thought that the outlay of so large a sum was a matter that the Committee of Council would be only too anxious that the members at large should be acquainted with. I regarded its omission as a mere oversight, which would at once be rectified.

I understand that I have been interpreted as throwing some doubt on the explanation of the President of Council, that the delay in publishing the report of the January meeting was accidental. I had no such meaning, and I should much regret to be supposed to have made any such imputation, which was entirely foreign to my thoughts.

I have the honour to be, sir, your obedient servant,

W. C. GRIGG, M.D.,

Honorary Secretary of the Metropolitan Counties Branch.  
6, Curzon Street, Mayfair, W., March 8th, 1878.

### THE LOST MEDICAL SCHOOL.

SIR,—The letter of Mr. Savory on the "Teaching of Natural Science in Medical Schools", published in your JOURNAL of March 2nd, though it contains no direct reference to the Universities of Oxford and Cambridge, is possibly intended, and has been interpreted, as a plea for the separation of the preliminary and the professional portions of medical study, so far as the old Universities are concerned. Mr. Savory has, in fact, been understood to advocate the view that, whilst it is desirable, even in the case of large London institutions like St. Bartholomew's Hospital, that only one of the two portions of medical study, namely, the professional, be attempted, and that London should have a distinct central college for the teaching of the preliminary (sometimes called the scientific or theoretic) subjects of medical education, it is similarly desirable, conversely, that Oxford, because it has a series of institutions for teaching those preliminary subjects, should not have an institution and arrangements for teaching the professional subjects such as are taught in hospitals.

I will not do Mr. Savory the injustice to suppose that he would himself argue in this manner; and clearly enough, as a matter of fact, he has not done so in his published letter. But, in view of the fact that such an interpretation has been put upon his letter, and that such an argument has been advanced by eminent London practitioners, I should wish to say a few words, in order to expose what appears to me to be a fallacy, seductive and symmetrical in form, but likely to be injurious to the great cause of University education.

That a hospital is not the proper place for the study of chemistry, physics, botany, physiology, and anatomy will probably be conceded by all who desire a complete medical curriculum to be established at Oxford and at Cambridge. It would be a great service to students and teachers alike were these subjects taught in London, under the auspices of a central University institution, to all the students now scattered in the various London hospitals, and were the physicians and surgeons of these institutions to abandon work which does not lie within their province, and to hand it over, through the agency of a central institution or university, to the most competent teachers. There is, however, no real parallel between such action on the part of a London hospital and the total abandonment of professional medical study by the University of Oxford. The former would be a retirement from an utterly inappropriate task; the latter would be a renunciation of a most weighty duty and privilege. In the one case, an institution would be beneficially restricted to its special functions; in the other, a far more important organ of the national life would be robbed of its most legitimate source of power and vitality. The University of Oxford is not a mere block of brickwork, with a few thousands a year and a secretary; were it so, the proposal that it should confine its connection with medical studies to the "preliminary subjects which can be so admirably studied in a country town" would be reasonable. Strange though it sometimes appears, the University of Oxford is, like the other great universities of Europe, a corporation solemnly charged from the most ancient times with the duties and the privileges of upholding the study and the teaching of three great departments of learning connected with the three great professions: the clerical, the legal, and the medical. For these purposes, she has at her disposal pecuniary resources which are practically boundless. To whatever extent her activities may now have been perverted and her resources misapplied, so long as Oxford retains her privileges she simply cannot renounce her duties to medicine. There is ample room for a distinct school of the professional portion of medical study in the city of Oxford by the side of the other institutions belonging to the University, and, when once the Radcliffe Infirmary is used under her auspices for clinical instruction by some hundred students, she will very probably proceed to annex, for the further use of her Medical Faculty, a London hospital or two.

I am, sir, yours faithfully, E. RAY LANKESTER, M.A., F.R.S.  
Exeter College, Oxford, March 1878.

## MANAGEMENT OF CONVICT PRISONS.

SIR,—A laborious and exhaustive inquiry into the management of our convict prisons is in progress by a Royal Commission. An investigation of this kind, conducted by such men as Lord Kimberley, Sir Henry Holland, Dr. Greenhow, and others, cannot fail to elicit the truth that there is scarcely a question within the scope of the inquiry which does not reveal the great extent of the medical officer's responsibility.

The machinery of such prisons as Millbank, Pentonville, Chatham, etc., would not work smoothly if experience, tact, and professional skill were wanting in the surgeons, whose decisions and opinions are in hourly request; and it is a reasonable ground of complaint that their services are most inadequately required. They had a right to expect that, in the recent appointments of commissioners and inspectors under the new Prisons Act, some of their number would have been nominated. They have a right, when the salaries of other officials in the department are augmented on the plea of increased work, to claim equal consideration on the same plea; and they have a fervent hope that on Dr. Greenhow, one of the Royal Commissioners, they may rely for a powerful representation of their important work, and for its more substantial recognition.—Your obedient servant,

A CLAIMANT.

March 11th, 1878.

## HARVEY TRICENTENARY MEMORIAL FUND.

SIR,—I am commissioned by the London Executive Committee of the abovenamed Fund to ask that you will be so good as to advocate in the columns of your influential journal the object for which this Memorial Fund has been established; and that you will also consent to receive at the office of the BRITISH MEDICAL JOURNAL the subscriptions of persons willing to contribute to the Fund.

About half the money (£1,600) required for the erection of a suitable statue of Harvey has been already subscribed; it is most desirable that the remainder should be forthcoming at once, as the three-hundredth anniversary of Harvey's birth will occur on the 1st of April in this present year.

I inclose a statement of the object of the Fund, and a list of subscribers up to the present date; and I beg to remain, sir, your obedient servant,  
GEORGE EASTES, Honorary Secretary.  
69, Connaught Street, W., March 13th, 1878.

\* \* We shall have pleasure in receiving subscriptions and handing them to the Treasurer of the Fund.

## "REGISTERED QUACKS."

SIR,—There is, I regret to say, an increasing class of legally qualified medical men who may simply be called "registered quacks", and who, as far as I can see, differ from the lowest and worst type of quacks in two particulars only: first, that they may be presumed to have had a fair professional education, and are, therefore, the more dangerous; and, secondly, that, since their names appear in due form on the official Register published under the direction of the General Medical Council, they are legally entitled to recover their charges from the victims who have fallen into their clutches.

I enclose for your edification the advertisements of two such persons, the one taken from a country newspaper (their favourite medium), the other from a high-class London weekly, in which, however, I am happy to say I have been able effectually to prevent its appearance for the future. Comment on these I leave to your discretion, and will confine myself to the remark, that the advertisements and pamphlets of these duly qualified and registered practitioners are couched in the usual terms of the "nervous debility" quacks.

Now, such things are probably well known to yourself, if not to the majority of your readers, and I draw attention to them only because I see no reason to hope that such abuses of an honourable profession are likely to be dealt with by the impending Bill for the amendment of the Medical Acts.

To those who think that a remedy exists I may state that, two years ago, I had, with regard to one of these persons, a long and futile correspondence. I gave proof of his proceedings, in the first instance, to the Deans of the several Faculties whose diploma he holds. One at once informed me that they were powerless to act, and referred me to the Medical Council; another was doubtful, but thought that Section 29 of the Act might apply; the third "hoped that this charlatan's name might soon be erased from the roll". In the end, however, it was found that nothing could be done. I then wrote to the General Medical Council. From an official of that august body I got a curtly

polite answer, to the effect that no steps could be taken. Yet no one could, I think, accuse that officer of any want of energy and activity; for, by the same letter, he begged to inform me that, under Section 14, I was myself liable to have my name erased from the Register. I had, as it happened, dated my communication from an address other than that registered. Perfectly satisfied with this proof of the careful watch kept by the Council over professional interests, I let the matter drop. Nothing, however, appears to have been done or suggested, and I am now induced, in the interests of the profession, to draw attention to this evil in your columns, feeling sure that, if any steps for its eradication be feasible, your powerful aid will not be wanting.—I am, sir, your obedient servant,

A. H. D.

March 11th, 1878.

PUBLIC HEALTH  
AND  
POOR-LAW MEDICAL SERVICES.

ONE of the relieving officers of the St. George's Union has been recently suspended by the guardians, on grounds which have been inquired into by the Inspector of the Local Government Board. As to the merits of the case against this official it is not our purpose to refer; we only comment upon the subject because the counsel for the official referred to thought fit to exceed the limits ordinarily accorded to the gentlemen of the long robe by a wanton, and, as it appears to us after reading the evidence, an absolutely unwarrantable, attack upon the *bona fides* and professional reputation of one of the witnesses subpoenaed by the Local Government Board. The learned counsel, by his attack upon Mr. Fenton, the Medical Officer of St. George's Union, has given another proof of the truth of the dictum, "If you have no case, abuse the principal witness". Mr. Fenton will survive this, as he has already survived other matters in the St. George's Union.

THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION,  
THE LOCAL GOVERNMENT BOARD, THE SAFFRON  
WALDEN BOARD OF GUARDIANS, AND  
MR. BUCK.

WE have received the following letter for publication.

"3, Bolt Court, Fleet Street, March 1878.

"My Lords and Gentlemen,—I am directed by the Council of the Poor-law Medical Officers' Association to bring under your notice the following case, as in the judgment of the Council it appears to be so unjust as to merit at your hands careful consideration.

"It would appear that, in April last, Mr. Buck of Newport, Essex, the medical officer of No. 3 District of the Saffron Walden Union, was required, by order of the relieving officer, to attend two children of a labouring man named J. Wright, residing at Rickling, Essex, and who had seven children under fifteen years of age, six of whom were dependent on him, the average earnings from all sources amounting to about sixteen shillings a week, out of which he has to clothe and feed his wife and children. In the harvest time he earns some twenty-five to thirty shillings a week for about six to eight weeks, which additional earnings enable him to pay his rent. There can, therefore, be no doubt whatever that this man was fairly entitled to receive parochial medical assistance. This, it would appear, was rendered by Mr. Buck, and the names of the children were duly entered on his medical relief book. Virtually, therefore, the Board of Guardians sanctioned the order of the relieving officer.

"In the month of December last, Mr. Buck was suddenly called to attend one of this man's children, who had fractured his leg. He went, as any medical officer of proper feeling would do, immediately to the child's assistance; and, having put up the fracture, directed the father to apply to the relieving officer for an order, which this official refused to give, but referred him to the Board. The father, thereupon, applied to the Guardians, who declined to grant him one, solely (as the Council believe) because the Guardians were indisposed to pay the fee which Mr. Buck would have been entitled to under the general orders of your Board. What adds to the injustice of this decision, is the fact that the Guardians of this Union direct Mr. Buck's attendance on the families of other labouring persons, in some instances earning more money and having fewer children to maintain. This statement can be substantiated on inquiry; but to resume.

"The Council is aware that your Board has decided that an order for medical relief only lasts so long as the illness of the person for whom it is given; but the Council would respectfully submit that, as the Guardians had recognised this man's impecuniosity in April, and had ordered medical relief, which cost them nothing, that this Board was morally, and, the Council think, legally, bound to grant an order in December, notably as the pecuniary position of Wright had not in the interval changed.

"It is true that it might be alleged that Mr. Buck should have waited for an order ere he attended to the necessities of this child; but the Council would submit that if such rule were to be generally acted on, it would tell very frequently with disastrous effects on the interests of the sick poor; and, indeed, the Council believe, and not without good grounds, that your Board would hold a medical officer censurable if he insisted on following a hard-and-fast line, and if death resulted from his refusal to attend without an order—notably, too, in a case where, as in this instance, an order had been given for his attendance a few months before.

"Nor is this all. The Council would respectfully submit that Mr. Buck was elected under the distinct intimation that he would be entitled, as an addition to his annual stipend, to all those extra fees laid down in your general orders, and the amount of which is more or less easily calculable in a given locality. The Council feel that if a Board of Guardians advertise that extra fees will be allowed, and then meanly refuses to grant them, and that, too, on account of a person whose pauperism has been admitted, that a very serious blow will be struck at the efficiency of the Poor-law medical relief system throughout the country.

"The Council trusts that your honourable Board will see fit to direct that the Saffron Walden Board of Guardians should pay the fee for the attendance of Mr. Buck on Wright's child.—We are, my lords and gentlemen, yours obediently,  
JOSEPH ROGERS, Chairman.  
"J. W. BARNES, Hon. Secretary.

"The Hon. the Local Government Board."

### ELECTION OF MEDICAL OFFICERS.

AN appointment has just been made in a country union, to which, in the interests of the sick poor and also in that of the Poor-law medical service, we feel it our duty to direct attention. In our advertising columns of the 2nd instant, we published an announcement that the guardians of this union desired to appoint a medical officer for a district of the union, the area being 5,869 acres, the population 1,853. Four candidates applied for the vacancy, one of whom lived in the district; disregarding this, the guardians elected a gentleman who already holds the second district, with an area of 22,159 acres and a population of 3,500, and the Workhouse; he also holds a district of another union, whose area and population, doubtless from prudential motives, are not given. The nearest point to the district to which the gentleman in question, in defiance of the regulations of the Local Government Board, has been thus appointed is five miles, the most distant is ten miles. What is contemplated by the Board of Guardians is evident. By law they are compelled to appoint a medical officer; but, by their selection, it is made manifest that the well doing of the sick poor confided to their guard has never entered into consideration. We are pleased, however, to record that the Vice-chairman protested against the appointment, assigning as his sole objection his sympathy for the well-doing of the sick. We heartily agree with him, and only hope that, as the Local Government Board can veto this appointment, it will exercise its authority and annul this election.

**VACCINATION.**—Dr. W. J. Treutler has received a Government grant of £9:8 for successful vaccination in the Maresfield District of the Uckfield Union.

### POOR-LAW MEDICAL APPOINTMENTS.

CLARKE, Thomas, L.R.C.P., appointed Medical Officer to the Third District of the Pewsey Union, *vice* F. H. Carter, M.R.C.S.Eng.

### MILITARY AND NAVAL MEDICAL SERVICES.

THE principal army veterinary surgeon reports that nineteen vacancies exist at the present time in his department; and that, with the present terms offered to the profession, it is impossible for him to find candidates of the proper social status to fill them.

### MEDICO-PARLIAMENTARY.

**HOUSE OF COMMONS**—Monday, March 11th, 1878.

**Cattle-Disease at Alford.**—In answer to Sir W. Lawson, Lord SANDON said: I am glad to say that we are assured that no further death has occurred from this disease. No claim for compensation has been made upon the Government; and as the disease does not come within the provisions of the Contagious Diseases (Animals) Act, 1869, no such claim could be made. I am informed that some of the food which had been partaken of by the cattle prior to the outbreak was analysed, and that no poisonous agent was detected in it. I ought to mention the cause to which the most experienced Inspectors of the Privy Council are inclined to attribute the disease; but I almost fear to shock the honourable baronet too much by doing so. However, I think I ought to inform the House that they think it probable that this very serious disease was induced by drinking-water.

**Vivisection.**—In reply to Mr. Pease, Mr. CROSS said that twenty additional licences had been granted beyond what appeared in the half-year's return. He had had many interviews with a most able inspector, who had assured him that there was not the slightest ground for believing that there had been any abuse.

### MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 7th, 1878.

Hope, William More, Piccadilly  
Nickolds, William Stephen, Shepherd's Bush  
Ross, Richard Alexander, Brighton  
Stuart, Henry Ogilvy, Woolwich

The following gentlemen also on the same day passed their primary professional examination.

Fenton, Frederick Enos, St. Mary's Hospital  
Hall, Thomas Lambert, Birmingham  
Oswald, Robert James William, Charing Cross Hospital

**UNIVERSITY OF DUBLIN: SCHOOL OF PHYSIC IN IRELAND.**—At the Hilary Term Examination for the Degree of Bachelor of Medicine, held on Monday and Tuesday, February 18th and 19th, 1878, the successful candidates passed in the following order of merit.

Neville, William C.	Daly, Ulick
Cowen, Edward J.	Malley, Abraham
Wilkinson, William C.	Tench, Charles H.
Young, Alexander G.	Smith, Thomas O.
Pentland, Alexander	Crofts, James G. W.
Egan, Constantine R.	Day, James D.
Inman, Arthur	

At the examination for the Degree of Bachelor in Surgery, the following was the order of merit in which the candidates passed.

White, Edward W. W.	Daly, Ulick
Mallins, Clement	Taylor, Rogers W. G.
Young, Alexander G.	Fogarty, Thomas F. W.

### MEDICAL VACANCIES.

THE following vacancies are announced:—

**BRISTOL GENERAL HOSPITAL.**—Physician's Assistant. Salary, £50 per annum. Applications on or before April 19th.

**CERNE UNION.**—Medical Officer of Health. Salary, £60 per annum. Applications on or before the 25th instant.

**DUMFRIES AND GALLOWAY ROYAL INFIRMARY.**—House-Surgeon. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 22nd instant.

**DUNFANAGHY UNION, Donegal.**—Medical Officer of Gweedore Dispensary District. Salary, £100 per annum, with £10 as Sanitary Officer, exclusive of Registration and Vaccination Fees. There are also two Police Stations and a Coast Guard Station in the district, which are usually placed in charge of the Medical Officer. Applications to the 17th instant. Election takes place on the 22nd instant.

**LINCOLN GENERAL DISPENSARY.**—Resident Medical Officer. Salary, £150 per annum, with furnished apartments, fire, and gas. Applications on or before the 16th instant.

**MANCHESTER ROYAL INFIRMARY.**—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Applications on or before the 31st instant.

**MILLSTREET UNION, Cork.**—Medical Officer of Workhouse, at a salary of £70 per annum. Applications, with Testimonials, to the 21st instant.

**NARBERTH UNION.**—Medical Officer for No. 4 District. Salary, £35 per annum, and fees, with £10 as Medical Officer of Health.

**STAFFORDSHIRE GENERAL DISPENSARY.**—House-Surgeon and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 26th instant.

**WEST SUSSEX, EAST HANTS, AND CHICHESTER GENERAL INFIRMARY AND DISPENSARY.**—House-Surgeon. Salary, £80 per annum with board, lodging, and washing. Applications on or before the 30th instant.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BLOMFIELD, A. G., M.R.C.S.Eng., appointed House-Surgeon and Secretary to the West Norfolk and Lynn Hospital.

LITTLE, William, M.D., appointed Honorary Surgeon to the Royal Southern Hospital, Liverpool, *vice* John Nottingham, F.R.C.S., Senior Surgeon, resigned.

RANSFORD, T. D., F.R.C.S., appointed Honorary Surgeon to the Royal Southern Hospital, Liverpool, *vice* T. G. Wollaston, M.D., resigned.

\*ROBINSON, C. H., F.R.C.S.L., appointed Medical Referee to the Great Britain Mutual Life Assurance Company.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

#### BIRTHS.

DAVIES.—On March 1st, at Preswylfa, Colwyn Bay, North Wales, the wife of Thomas Davies, L.R.C.P. Edin. & M.R.C.S. Eng., of a son.

\*JAY.—On March 12th, at Chippenham, Wilts, the wife of Henry Mason Jay, M.B., F.R.C.S., of a daughter.

PARSONS-SMITH.—On March 8th, at St. John's Lodge, Addiscombe, Croydon, the wife of \*S. Parsons-Smith, L.R.C.C.P., of a son.

#### DEATH.

\*DORRIS, James, M.D., F.F.P.S., of 2, Great Kelvin Terrace, Glasgow, at Morton Villa, Dumfries (the residence of his mother), on February 26th.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY**..... Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

**TUESDAY**..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY**.. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Erompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY**.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

**FRIDAY**..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY**.... St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**.—Medical Society of London, 8.30 P.M. Mr. Squire, "Two Cases of Flat Vascular Naevus successfully treated by repeated Linear Scarifications"; Dr. Sullivan, "On the peculiar Function of the Spleen, and the influence of Malaria upon it".

**TUESDAY**.—Pathological Society of London, 8.30 P.M. Meeting for the Exhibition of Specimens illustrating Diseases of the Lymphatic System, including Lymphadenoma and Leukemia. Specimens will be shown by Dr. Wilks, Dr. Gowers, Dr. Greenfield, Dr. Goodhart, Mr. Nunn, Dr. R. Jones, Dr. Whipple, and others.—Statistical Society, 7.45. Mr. C. Walford, "On the Famines of the World".

**WEDNESDAY**.—Association of Surgeons Practising Dental Surgery, 8.30 P.M. Ordinary Meeting.

**THURSDAY**.—Harveian Society of London, 8 P.M. Dr. Edis, "Cases illustrating the Diagnosis of Abdominal Tumours"; Dr. Ashburton Thompson, "Cases of alleged Maternal Impressions".

**FRIDAY**.—Clinical Society of London, 8.30 P.M. Mr. Hutchinson, "Retinitis Hemorrhagica: its connection with Gout, and probatic dependence upon Thrombosis of the Vein". Dr. Broadbent, 1. "Unusually rapid Effusion of Fibrinous Fluid into the Pleural Cavity at the age of 76: Paracentesis: Recovery"; 2. "Pleuritic Effusion: Sudden Death without Paracentesis". Mr. Nunn, 1. "Electrolytic Treatment of Epulis"; 2. "Plantar Bunion".—Quekett Microscopical Club (University College, Gower Street), 8 P.M. Ordinary Meeting.

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

## SEVERE VOMITING.

SIR,—Can any of your readers, from experience in similar cases, suggest further remedies in a case of chronic vomiting, lasting over five years, with every now and then attacks of great prostration and vomiting of a greenish membranous substance, and great pain over the stomach? The patient cannot retain anything; and even a teaspoonful of champagne is returned, and causes great distress. For months I have given pills of two and three grains of opium (crude), or a quarter of a grain of morphia, but now even these cause vomiting. Enemata are not retained, and the slightest movement brings on the attack. Blisters will not take effect, to allow absorption of morphia. Hypodermic injections cause large abscesses. I have tried pills of extract of meat, but with no better result. Oxalate of cerium, kousm, lead and opium, poultices with opium, chlorodyne, carboic acid, etc., have been used, but nothing can be retained. The only thing that can be retained, and that only for a short time, is ice and lemon. The attack has been on some weeks, and necessarily there is great exhaustion.—Truly yours,

M.R.C.S.

MR. WALTER L. RANKIN will receive the necessary form of application for membership.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a Post Office.

## PICTURES FOR LOCK HOSPITALS.

A CORRESPONDENT writes:—The desirability of making the wards of our hospitals as cheerful as possible is now generally admitted. As a very general rule, their walls are now decorated with pictures, illuminated texts, mottoes, and other means for relieving the bare appearance they would otherwise present, and with which we were formerly too familiar. The liberality of the public has been well illustrated in providing the necessary funds, and more especially in the case of hospitals and infirmaries for children; indeed, it may be said that pictures for such hospitals have only to be asked for, to be obtained at once and in abundance. There is, however, one class of hospitals which, for obvious reasons, are not likely to be equally favoured, except by a strong and special appeal. We refer to lock hospitals. These cannot be open to the public, nor can appeals to the public be made on behalf of their inmates with the same confidence as for the patients of any other medical charity. Some time ago, the proprietors of the *Graphic* issued a notice offering to send engravings and back numbers to any hospital or infirmary on a request being made from the managers of such institution. Seeing this, Mr. F. W. Lowndes, surgeon to the Liverpool Lock Hospital, applied on behalf of that institution, the walls of which at that time presented a rather bare appearance, and in due course a large parcel arrived at the hospital, which was found to contain a number of very handsome engravings of various sizes, both plain and coloured, together with many back numbers. With the assistance of a few influential subscribers, Mr. Lowndes succeeded in raising a sum sufficient to place the engravings in neat oak and glass frames of the "Oxford" pattern. The improvement in the appearance of the wards was very marked; and it affords us sincere pleasure to record so generous and pleasing an act on the part of our pictorial contemporary. It is on all accounts most desirable that the wards of lock hospitals, especially those of a voluntary character, should be made as cheerful and attractive as possible.

## SUCKING THE TONGUE.

SIR,—Can any member give me an idea as to how to prevent a child of three years of age from sucking its tongue? I have looked at the usual standard works, but I see no mention of it there. The habit, of course, will be given up as time goes on; but I should be glad of any hint on the subject from any of the readers of the *JOURNAL*.—Yours faithfully,

A MEMBER.

## A VOICE FROM JAPAN.

SIR,—As a contribution towards the formation of a sounder public opinion upon the pedestrian feats which seem to be becoming more fashionable, will you allow me, as a reader of the *BRITISH MEDICAL JOURNAL*, to enter my protest against medical men lending any countenance to these exploits, which seem to serve no other purpose than to gratify the vulgar vanity of the performers and their admirers? If any physiological problem were to be solved, or any other good purpose served, it would be the duty of the medical attendant to place the performer in the most favourable circumstances for performing the experiment, and there would attach to the experimenter the heroism of self-sacrifice for the good of humanity. In such a case, also, one experiment, carefully conducted, would suffice; but it appears that there is no more worthy object than for one pedestrian to outdo another in reducing himself to a walking machine. Under these circumstances, it appears to me to be the duty of any medical man who may be summoned to attend the pedestrian, absolutely to forbid his "patient" to expose himself to the risk which is involved in the performance of such a feat as "walking four thousand quarters of a mile in four thousand consecutive ten minutes". Supposing the feat accomplished, every sensible man will think the pedestrian a great fool for his pains, and every right feeling man will pity him that he cannot find some more worthy cause to which to exercise his powers of physical endurance. And surely if the feat be attended by any evil consequences, the medical man who has promoted it must be held responsible. It seems to me to be the duty of the medical profession to frown down these contemptible exhibitions, and not to pretend that they are done in the cause of science, or in any way to throw around them the halo which attaches to an act of sacrifice in the sacred cause of scientific investigation.

These remarks are suggested by a report of the pedestrian feat of William Gale, recorded in the *BRITISH MEDICAL JOURNAL* of November 10th, 1877, in which it represented that certain physiological elements are demonstrated. I doubt whether any new physiological fact is demonstrated; and, granting even that it is, I hold that "the game is not worth the candle". I should like to see the influence of the *BRITISH MEDICAL JOURNAL* directed against these proceedings, which are, in my opinion, essentially vulgar, contemptible, and demoralising.—Yours truly,

Niigata, Japan, Jan. 23rd, 1878.

THEONALD A. PALMER, M.A., M.B.

\* \* \* The observations made by Austin Flint, Pavy, Mahomed, and others on those occasions have been of great scientific value.—Ed. B. M. J.

Will Dr. Garney kindly inform us, in reference to the communication which he forwards this week, what is the composition of the substance which in his report he describes as phosphodia, and where Dr. Klein recommended it for the treatment of cancer?

## MEDICAL TITLES AND THE NEW MEDICAL ACT.

SIR,—A *propos* of the Duke of Richmond's contemplated Medical Amendment Act, will you permit me to suggest that any such measure will be very incomplete which does not conclusively deal with that incessant bone of contention among general practitioners—medical titles. Either that all qualified medical men should, as in France, be dubbed "Doctor", or, on the other hand, that the Licentiates of Colleges of Physicians should be decisively prevented from encroaching on the very barren and often hard-won honours of the medical graduates, is a solution of the difficulty devoutly desired, I believe, by many others beside your obedient servant, March 10th, 1878.

M.D. Lond.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### LADY-MEMBERS OF THE ASSOCIATION.

SIR,—When Dr. W. O. Markham wrote his apologetic letter, he might have taken the trouble to refer to the by-laws of the Association. I am surprised that so many write letters, and cull from imagination alone. Mrs. Anderson and Mrs. Hoggan were admitted members contrary to the rules; and unless Dr. Markham can find a loophole in the by-laws, they are not entitled to membership now, and never were. If a female become "*he*" after obtaining a medical qualification, then I confess we must submit to the admission of "*ladies medical*" as members; but according to the existing laws, only *he's* are eligible, not *she's* at all. As many members may not possess a copy of the Articles of Association and By-laws, and in order to show that no motion or resolution is required for the expulsion of Mrs. Anderson and Mrs. Hoggan, I shall give the three paragraphs bearing upon the election of members from page 15 of said articles, etc.

"*Election of Members*.—1. Any qualified medical practitioner not disqualified by any by-law of the Association who shall be recommended as eligible by any three members, may (subject as hereinafter mentioned) be elected a member by the Committee of Council, or by any recognised Branch Council.

"2. No person shall be elected a member unless *he* has the votes of not less than three-fourths of the members present at the meeting of the Committee of Council or Branch Council at which *he* is proposed for election, and has agreed in writing to become a member, and to pay *his* subscription for the current year.

"3. Any member may be expelled from the Association by a resolution of the Committee of Council if carried by three-fourths of the members present, subject to confirmation by the next annual meeting; and *he* shall thereupon cease to be a member, and shall not be eligible for re-election. One month's notice of the intention to propose such resolution shall be given to any member affected thereby."

I have put *he* in italics, to show nothing can be more plain than the wording of these by-laws. Dr. Markham says: "All, therefore, required is, that proper steps be taken to frame a law, which shall meet the wishes of the majority of the Association." The law is already framed, and the Committee of Council have simply to let Mrs. Garrett-Anderson and Mrs. Hoggan know that their election was a mistake, and that females are not eligible as members of the British Medical Association. Let this be done at once, seeing the two ladies are unwilling to resign, and save the Association from unseemly bitterness and ignoble squabbles over this job, which should never have seen its present development had the Committee of Council acted according to the by-laws of the Association. Dr. Markham is altogether wrong when he says: "These ladies were admitted in accordance with the laws of the Association; and, until better informed, I conclude that they cannot be legally ejected from the Association." The by-laws above quoted will surely convince Dr. Markham that "these ladies" have no right to membership; and No. 3 gives power to expel even Dr. Markham, myself, or any other member, according to "club law", and we have no power of appeal but to the annual meeting. In No. 2, above quoted, the word *he* occurs twice, and *his* once; the ambiguous term "person" not at all referring to *she's*, but *he's*.

No new law is required to decide "that ladies shall not be admitted in future", for, according to the by-laws, they have no claim, and are "out of court". By all means return them their subscriptions. If they do not retire, and the Committee of Council fail to carry out the laws of the Association, I shall give notice and have the question brought before the next annual meeting, and demand from Dr. Falconer and his confederates an account of their stewardship in this matter. We have line upon line bearing upon this point, yet nobody has troubled himself to look into the by-laws concerning this question. I have written to Dr. Falconer, calling his attention to the subject, and I hope at the next meeting of Committee of Council the "lady question" will have some consideration, and, ere long, the retirement of Mrs. Anderson and Mrs. Hoggan will be announced.

I should indeed be sorry to wound the feelings of Mrs. Anderson or Mrs. Hoggan; but so long as dissatisfaction prevails, and seeing they have no right to membership according to the by-laws, I must, as a member, insist upon either their retirement or expulsion from the British Medical Association, and it will then be open to Dr. Markham and others to bring in a resolution in order to admit ladies, if they think fit, and, for the welfare of medicine and the Association, desirable.—I remain, yours very truly,

HENRY BROWN.

Northallerton, March 9th, 1878.

M.D. BRUSSELS.—Will any of your readers who has obtained the degree of "M.D. Brussels" kindly inform me what books are the best to take up on each subject of examination?

IFAN.

THE following communications have been handed to the General Manager:—Mr. Charles Rogers, Retford (with enclosure); Dr. J. Christie, Glasgow (with enclosure); Mr. W. Moorman, St. Colomb, Cornwall; Mr. E. McGrath, Kierke, Bombay; Mr. Henry Fox, Bristol; Dr. H. M. Jay, Chippenhams (with enclosure); The Secretary of the Mochra Coffee Company; Mr. Walter L. Rankin, Strathblane; Dr. R. H. Allnatt, Frant.

#### GLAUCOMA.

SIR,—I should like to lay before those who are best able to judge the following propositions, apologising for the somewhat bald manner of putting them. 1. Is glaucoma simply a hydrocele of the aqueous chamber of the eye? 2. Is iridectomy curative, accidentally as it were, by means of iritis, just as inflammation excited in the secreting membranes of other hydroceles is curative?—I am, etc.,

S. WILSON HOPE.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### AN APPEAL.

SIR,—May I venture to ask you to insert my appeal in the next issue of the JOURNAL on behalf of a medical man now lying helpless from accident and disease? The facts are shortly as follows. Mr. W. H. Barber, L.R.C.P. Lond., of this town, has for the last three years been unable to follow the active duties of his profession in consequence of an accident, whereby he lost the entire use of his right arm. For some months past he has been under my care, suffering from partial loss of power in the lower extremities, and has been during the whole of this period confined to his bed. He is now, I find, without adequate means for his support, having been unable (like too many of us) to make provision for a rainy day out of a slender and laborious country practice. I propose making an appeal on his behalf to the profession, hoping by so doing to secure for him that amount of comparative ease and comfort during the remaining portion of his life which I would earnestly desire for myself or for others who might be so unfortunately placed.

The merits of the case for which I plead are well known to, and can be attested by, the Rev. Boscawen Somerset, M.A., Rector of Crickhowell, and the Rev. George Howell, R.D., Rector of Llangattock.

Any contributions will be thankfully received by me, and, with your permission, acknowledged in the JOURNAL.—I am, sir, your obedient servant,

PHILIP E. HILL, M.R.C.S. Eng., Surgeon to the Crickhowell Dispensary, etc.

Crickhowell, March 9th, 1878.

SIR,—Can you advise a member of the British Medical Association whether he would be justified in admitting a man aged 27 to a small benefit club? The man has been deaf and dumb from birth; in other respects healthy; both parents alive; no other member similarly affected. The man by occupation is a gilder.—I am, sir, faithfully yours,

B. J. A.

#### PHYSICIANS' FEES.

SIR,—I have waited in hopes that some other correspondent would have adverted to the one point which, more than any other, affects the general question of medical fees—the value we ourselves put upon our own services. The discussion began with a complaint that well-to-do patients were apt, whenever possible, to diminish or evade physicians' fees. Doubtless these "well-to-do" people reason in this way: "I find I have no money to spare; the expenses of life have doubled during the last twenty years, and the necessities of luxury have increased. I can ill afford to spend unnecessary money; and why should I pay high fees for as little, or less, skill and attention as thousands of persons no worse off in their place in life than I am in mine can have for nothing?" Of course, they ought not to reason thus; they ought to feel that their high payments barely compensate the physician for the hours a day he devotes to the poor and needy. But theirs is the reasoning of the world; it begins and ends at home. The fact is, the world takes us much at the value we place upon ourselves; and the time, attention, and skill given gratuitously at the hospitals not only lessen the amount of physicians' fees, but have their ulterior effects in depreciating the services of our brethren in every town and village, and wherever a general practitioner has fairly worked; but to die in harness and leave his family without provision, some portion of the blame is shared by every surgeon and physician who systematically gives away day by day, on a large scale, what is the equivalent of bread and meat, clothing and lodging. This is not the place to discuss the well known evils of promiscuous medical charity; they are generally recognised. But I would pass on to ask, Does Christian philanthropy require from us this systematic sacrifice of our time and strength? No. The good Samaritans of the present day build and endow hospitals, and then say to the doctors, "Now, you come and attend to the people for nothing." The good Samaritan of Scripture took his sick man to an inn, but did not say to the host, "You attend to him for nothing"; but he paid him at the time, and pledged his credit to him for the future. Or, to alter the comparison, and find a parallel to the acts of the good Samaritan in our own gratuitous professional attendance on the poor, the good Samaritan is not put forward as an example of anything, but the meritorious conduct of a man who casually met and relieved the wants of another. We systematically work for nothing; and the practical effect is simply to enable people to do half their charity vicariously, at another's cost and not their own. We are often told that our profession is a noble one, although its nobility has never yet led to a peerage. It is a noble one, and its work would not be less noble if it were better paid. This much is certain, that as time goes on, and the value of money continues to lessen, the necessity for a revision of medical fees will become more and more apparent. The way to revision lies through the hospitals, and, this road once clear, the power will be in the hands of the heads of the profession, who will be able to put in force, within certain reasonable limits, any scale of fees they choose; and in proportion to the monetary value put upon their services by the leading physicians and surgeons will be the remuneration right through the profession down to the holder of the smallest union appointment and the poorest club.—I am, etc.,

March 1878.

ME QUOQUE.

SIR,—I am a practitioner of medicine, surgery, and midwifery to the general public in a small town in the North of Scotland, and I am of opinion that the general public aforesaid avoid paying me my lawful and reasonable fees whenever they have a chance of so doing. I will, therefore, thank any gentleman conducting a practice of this nature who will give me some idea as to how he obtains payment for the following: 1. Consultations with other medical men; 2. Midwifery—natural and instrumental, or complicated; 3. Visits in town; 4. Visits to the country; 5. Minor operations; 6. Major operations; 7. Advice at his own house. I also wish to know how he treats those who year after year neglect to pay their bills. I likewise desire information as to the difference in fees between, say, a large farmer and his farm-servants. In the event of any one replying, I will publish, in return, my present charges.—I am, yours, etc.,

PILGRIQUE.

SIR,—In your paper of the 2nd March, you publish a letter on the above subject, from "A Junior", who, whatever be the merits of the remainder of his communication, expresses sentiments in the second paragraph respecting gratuitous attendance on one doctor by another, which, I trust, are not those of any but a small minority of the profession. He says, "Why should I treat another medical man gratuitously?" and goes on to argue that, because clergymen and lawyers charge one another for professional work, we should do the same. The fact of clergymen and lawyers displaying niggardliness towards each other is no reason why we should do so too; and if all that can be said against one profession as compared with the two others be, that we are more charitable than they, we may be content to rest under the imputation. When a medical man, perhaps considerably my senior, does me the honour to consult me, he confers at least as much obligation on me as I do on him by giving him my services; and most of us would view with much regret any departure from the custom. "A Junior" says that he and his wife

were badly attended by medical brethren until they got advice *incognito* and paid for it, and that after that "the improvement in attentiveness was most marked". It is not worth while to elaborately refute the unjust charge against an honourable profession which is implied in this remark; and, indeed, to do so, it would be necessary to accept the position that the inattentive brethren whom "A Junior" first consulted were a fair type of the members of the medical profession—a position which is of course untenable.—I am, etc.,  
F.R.C.S.

#### ATTENDANCE ON THE FAMILIES OF MEMBERS OF THE PROFESSION.

SIR,—Allow me to ask the opinion of the profession under the following circumstances. I must premise by stating I am L.R.C.P. and M.R.C.S. of twenty-one years' standing, during the whole of which time I have been in active practice, when it has often been my lot (and I consider duty and pleasure) to render professional aid to my professional brethren and their families without fee or expected reward; although, as a rule, I was paid in some form. Nor have I been less indebted to our noble profession in their kindness and attention to my wife and family, especially during a long residence abroad, as also to myself during two severe illnesses, consequently I have always given and accepted such aid as a matter of course; but I have lived to be enlightened on the subject by a junior practitioner, and do not feel inclined to pay without eliciting an expression of opinion. Many of my medical friends think the bill a mistake, and advise me to treat it as such. The simple facts are as follows. My daughter, aged 15, goes to school at some distance from me. Last summer, she had an attack described by her attendant as "hysterical." I received with the school account an enclosure at midsummer for £3 10s. 6d. for medical attendance (about a week). When I enclosed the check for schooling, I wrote the mistress that it was an error, doubtless made by the firm's clerk, and I took no notice of it. The other day I received another one through the same source, and await advice how to act, as I would not like to form a precedent for a less fortunate brother practitioner.—I am, sir, yours truly,  
March 1878.

MEMBER.

#### REMOVAL OF FOREIGN BODIES FROM THE AUDITORY CANAL.

SIR,—I have to thank Dr. Cassells for the name of the inventor of the "agglutinative" method; and as I have not claimed any originality for the plan adopted by me, or priority in the use of it, I should not further notice his letter were it not that Dr. Cassells, in saying he "described" the method in the *JOURNAL* of December 26th, 1874, contradicts one of my statements. I think, therefore, it best to let your readers know what Dr. Cassells has said on that occasion, and let them judge whether he has described the method or not. In his lecture, as reported in the *JOURNAL*, all I can find on the subject is contained in the following sentence. "I cannot allow this opportunity to pass without commending the excellent agglutinative method recently proposed by Löwenberg, the distinguished Parisian otologist, as one that offers a fair prospect of success when the simple means presently to be mentioned have failed to effect the purpose of the surgeon. In his (Löwenberg's) hands, in one case, it sufficed to accomplish the removal of a foreign body irremovable by every other means." Dr. Cassells then gives ten cases, in not one of which he used this method for removal of the foreign body.

My objects in sending the communication to you were, to recommend to the notice of the profession a simple and safe method of treatment for what are very often embarrassing cases, and to point out the superiority of a quick-setting cement over glue or wax, which can be used in the same way. I thought the knowledge of it might be useful to many busy men who, like myself, have not the opportunity of consulting *Monatschrift* or *Arch. für Ohrenheilk.*, and who do not enjoy the friendship of Löwenberg, and who may not consider that Dr. Cassells has given a very full or lucid description of the agglutinative method.—I am, yours truly,  
Castlewellan, co. Down, Feb. 25th, 1878.  
GEO. GRAY, M.D.

#### THE LATE SIR W. STIRLING MAXWELL.

SIR,—In answer to the letter of Dr. W. T. Black, which appeared in the number of January 26th of your *JOURNAL*, I can say that Sir W. Stirling Maxwell, Bart., did not contract "a fever in some of the canal-girt palaces of the old city"; but that when he arrived in Venice from Florence, on the 6th January, he had not been well for some days, and suffered from diarrhoea. His doctor, M. Levi, did not see him until three days later, when he presented high fever, pulmonary oedema, and enormous tympany. Dr. Levi was told that, although very much worse on the 7th and 8th, Sir W. Stirling Maxwell was out for the greater part of the day in an open gondola, and ate almost like a healthy man, which contributed a great deal to make worse his intestinal condition. Dr. Levi has written a detailed report of this malady for the friends of Sir W. Stirling Maxwell. I only know that he prescribed at first some mild aperient, a light tonic diet; and that later, it was necessary to have recourse to calomel, local cold baths, and turpentine injections. Sir W. Stirling Maxwell grew worse on the 13th and 14th, and died on the 15th. He was only sixty years old, but he looked as if he were seventy.

Now, I am rather surprised to see that Dr. Black thinks that the prevailing prejudice "against the professional ability of the Italian medical practitioner" will be rather increased by the death of our beloved King Victor Emmanuel, and by that of Sir Stirling Maxwell. I think that no English medical man can draw from these data such an inference against the ability of the Italian practitioner. If it were so, we should think, with more reason, that this is quite in opposition to the British calm and gravity.—Faithfully yours,  
Padua, 1 Feb. 26th, 1878.  
C. RUATA, M.D.

#### REMOVAL OF CHRYSOPHANEIC ACID STAINS FROM LINEN.

SIR,—I have been very frequently asked, and the question has been put to me more than once in the columns of this *JOURNAL*, What will remove the apparently indelible brown purple stains which disfigure the linen of patients who have been treated with chrysophanic acid ointment? This is the one drawback that now remains to the employment of this most serviceable remedy in psoriasis. All the other drawbacks to its use are, as I have recently endeavoured with some detail to show, eliminable by the exercise of a very little care (*in the treatment of Psoriasis by an Ointment of Chrysophanic Acid*, pp. 59, 60 (London, 1875)); but this particular disadvantage I have been obliged hitherto unreservedly to admit. I applied a short time since to the chief assistant of "Maison" or "Gon" powder, and he suggested to me acetic acid, or even vinegar. I accordingly tried acetic acid on a very representative towel, which, having been recently in use at the British Hospital for Diseases of the Skin, I had undergone a considerable discolouration by chrysophanic acid. To a part of this towel I applied strong acetic acid very thoroughly; this produced no effect. To another part of this scum had brown-purple towel I applied aqua fortis diluted with twelve parts of water. This only varied the hue to a brighter brown colour, without diminishing totally the intensity of the colouration. These results I communicated to my friend, who replied that chrysophanic acid was discoloured in the test-tube by acetic acid, and that he could

only therefore conclude that in the fabric of the linen it became a true "fast dye". Thrown by this rejoinder on my own resources, I next tried the aqua chlori, *P.B.* (chlorine water). This reagent at once removed the colour. I accordingly procured some common bleaching powder of the nearest oil-man. I determined to push the action of the agent without regard to the integrity of the towel. I accordingly made a strong mixture of the bleaching powder with very hot water, and immersed the towel in the liquid at ten o'clock this morning. After I had finished my morning's work I proceeded to examine the result, and at three o'clock this afternoon fished my towel out of the water on the end of a stick; but the stick, a blunt one, went through the towel, which would scarcely hang together as I lifted it out of the water. The towel was thoroughly rotted, but it had become perfectly bleached. No trace of the brown purple stains remained on the now perfectly white towel. I knew by the strength of which I employed the bleaching solution that I should rot the towel very completely, but I was not quite sure that I could so thoroughly bleach it. I have no doubt whatever that a more temperate employment of the bleaching solution—employed, for example, of such strength as washerwomen commonly use it—would bleach as effectually without rotting the linen. My reply, therefore, now to my numerous inquirers as to how to remove the stains of chrysophanic acid on the linen is, that they should have the linen properly—that is to say, moderately—bleached, by means of a dilute solution of bleaching powder in the usual way.—I am, etc.,  
March 1st, 1878.  
BALMANNO SQUIRE, M.B.

#### IS LIFE WORTH HAVING?

SIR,—My conscience has been much troubled by the remarks in an editorial of the *Spectator* of the 16th February on the decision of the High Court of Justice in a case of "cruelty to animals", deciding that it was cruelty to keep a mare alive for the sake of an expected foal when suffering from a hopeless injury to the leg, causing her great torture when she moved about, and stating that it would not be justifiable even to keep her alive in a stall, for that the suffering, though alleviated, would still be great. The editorial concludes: "If the statute does not contemplate as cruelty the case of purposely keeping alive, for gain, a creature whose life is torture, surely the statute ought to be amended." Now, I am afraid I and many of my *confères* have been guilty of keeping not only a creature, but a human creature, alive—if not for gain, at any rate to our gain—where life is torture. Will some experienced casuist kindly give me his advice as to whether we are justified in so doing, or whether we ought to shoot them at once?—I am, etc.,  
M.D.

DR. H. QUILL will perhaps kindly quote the suggestion of Dr. Cleland for the removal of foreign bodies from the ear.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Courant; The Middlesex County Times; The Liverpool Evening Albion; etc.

\* \* \* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

# THE GOULSTONIAN LECTURES ON THE LOCALISATION OF CEREBRAL DISEASE.

*Delivered at the Royal College of Physicians of London.*

By DAVID FERRIER, M.D., F.R.S., F.R.C.P.,  
Professor of Forensic Medicine in King's College; Assistant-Physician to King's  
College Hospital; etc.

## LECTURE I.—*March 15th.*

MR. PRESIDENT AND GENTLEMEN,—In these lectures, I propose to discuss a question which is at present attracting considerable attention in the world of physiology and medicine; viz., whether different regions of the cerebral hemispheres have different functions, and whether, therefore, the symptoms of cerebral disease vary with the locality of the lesion.

Assuredly, if the problem before us had been an easy one, it would have been definitively solved long ere now, when we consider the frequency of cerebral diseases and the large amount of attention they have received, not only from physicians and physiologists, but from all who interest themselves in the relations between body and mind. But, notwithstanding all the laborious researches and speculations which have been directed towards the elucidation of this subject, we do not seem even yet to have arrived at any general agreement, except on a very few propositions; some of these even now contested: a position contrasting strongly and unfavourably with the state of our knowledge respecting almost every other organ and function in the body.

It is not very difficult to discover many causes of this obscurity and confusion. Two of these only I will mention as being specially worthy of note.

1. It may be asserted without fear of contradiction that, as regards the nervous system more particularly, morbid anatomy is far from being co-extensive with pathology. We know, and are every day confronted with the fact, that the most widely abnormal deviations from healthy functional activity of the nerve-centres may be manifested, which leave no trace discoverable by ordinary dissection, or even by any of our most advanced methods of investigation. For the sake of mental satisfaction, we are constrained to speculate on the intimate molecular changes in the nerve-tissues which lie at the root of neuralgia, convulsions, and various other forms of functional nervous disorder; but they are at present matters only of speculation, and lie beyond the sphere of verification.

2. The organisation and conditions of activity of the brain are such that we are naturally inclined to believe that interference at any one point must necessarily tend to general functional disturbance. The loosening of a pin in a chronometer, it has been said, will derange the whole timekeeping mechanism; but we should not on that account ascribe timekeeping functions to the one part exclusively. So, in all cases of cerebral disease, there is a continual source of doubt as to whether the effects are the direct consequences of the lesion, or merely the expression of general functional derangement.

And, when we examine the actual facts and records of cerebral disease, we find, in apparently similar conditions, so much diversity, that it seems almost impossible, from a clinical point of view, to separate accidental from essential; to distinguish between direct and indirect consequences; or to determine whether phenomena are related by causation or are mere cases of juxtaposition or coexistence. Nor do the facts of experimental physiology seem so consistent with themselves, or with the undoubted facts of clinical research, as to inspire us with unhesitating confidence as to their accuracy, or as to their applicability to human pathology.

It is not to be wondered at, therefore, that many should still doubt, and reserve their opinion on this question of the localisation of cerebral function and cerebral disease.

Before proceeding to consider the facts bearing on this question, I think it advisable, in view of certain arguments which have been advanced by Dr. Brown-Séquard and others, to state some of the principles which must guide our researches and determine our conclusions. There can be no doubt that the inductive method of agreement, on which we have mainly to rely in eliminating cause and effect in clinical medicine, is one which does not always succeed in distinguishing between causation and co-existence, and is liable to be frustrated by plurality of causes. Though, therefore, we should have much positive

evidence in favour of the localisation of a certain function in a certain region of the cerebral hemispheres, one clear case in which destruction of this region had caused no cessation or disorder of that function would be sufficient to overturn our conclusion.

But, on the other hand, we are not called upon, in the present state of pathology, to show organic alteration in the parts in which we localise certain functions in all cases in which these functions are deranged. When such organic change has been demonstrated in the case of disordered function everywhere else in the body, it may fairly be demanded in the case of the nerve-centres; but we are at present far from having reached that point. We do not always discover organic disease in the heart when the circulation ceases, but we do not on that account doubt that stoppage of the heart was the proximate cause of this effect.

The doctrine of cerebral localisation does not assume, as Brown-Séquard would seem to imply, that the symptoms observed in connection with a cerebral lesion are necessarily the result of derangement of function in the part immediately affected. Every one admits direct and indirect results in cerebral disease. We have no right even to assume any causal relation at all, direct or indirect, between the phenomena, unless the lesion in question is constantly, or more frequently than chance would account for, associated with the same symptoms.

We should think it in the highest degree absurd if anyone were to describe a case of sudden death, in which the only discoverable morbid appearance was a boil on the neck, as a case of sudden death "seemingly caused" by a boil on the neck; and for the obvious reason that such a lesion is not usually followed by a fatal result. So, if we have abundant evidence to show that a certain part of the brain may be diseased without causing any motor paralysis whatever, it would be no less absurd to describe a case of facial paralysis, in which some lesion of this region was the only discoverable anatomical change, as a case of facial paralysis "seemingly caused" by this lesion. Causation must not be invoked where, the facts do not warrant anything beyond co-existence or fortuitous collocation. It is, however, undoubtedly true that, if we admit, as we must do, that function may be disordered without discoverable organic change in the organ in which we localise this function, our difficulties as regards diagnosis are greatly multiplied. In medicine, thanks greatly to the aid of experimental physiology, the transition from cause to effect is comparatively easy; but from effect to cause, from symptoms to disease, taxes all our skill, and too often baffles all our efforts.

We may have doubts as to our diagnosis of the nature and locality of a cerebral lesion, though we may have none as to the localisation of function. The two things are quite distinct; and we must not make our imperfections in the one a measure of the other, or imagine that the facts are equally confused with our notions respecting them.

In estimating the value of evidence, we regard as incredible any statement which is opposed to sound inductions. Our inductions having been once established, we attach comparatively little importance to individual instances which harmonise with them; for, not being necessary to establish our generalisation, they derive a dignity mainly from the fact that they are examples of a general law. But a statement which contradicts our uniform experience we are bound to regard with suspicion and refuse to accept, unless it can successfully stand a stringent cross-examination and satisfy all the requirements of scientific evidence. The slightest doubt is absolute failure. If, however, any clear and in every way satisfactory evidence be forthcoming opposed to our generally accepted beliefs or traditions, we are, nevertheless, bound to accept it, and be prepared to convert what we have been accustomed to regard as absolute rules into approximate generalisations, or abandon them altogether if they are clearly shown to be untenable.

Even though the new hypothesis which may be set up in place of our old one may not be more satisfactory, yet the value of the facts will remain, and we must modify our views in accordance with them.

In discussing the localisation of brain-function, it is essential to bear in mind that the functions and diseases of the brain manifest themselves under two aspects—the psychological and the physiological: phenomena which appeal to two distinct methods of investigation—the subjective and the objective. There is no doubt that the state of our knowledge respecting the conditions affecting the one is vastly in advance of that of the other.

That the brain is the organ of the mind, no one doubts; and that, when mental aberrations, of whatever nature, are manifested, the brain is diseased organically or functionally, we take as an axiom. That the brain is also necessary to sensory perception and voluntary motion, is also universally admitted; and that the physiological and psychological are but different aspects of the same anatomical substrata, is the conclusion to which all modern research tends. Nevertheless, it appears, as

far as our present methods of investigation have gone, that diseases of the brain do not affect these functions equally. Diseases which produce very obvious affections of motility and sensibility cause no obvious mental disorder; and diseases capable of producing the most profound mental disturbances do not necessarily affect the powers of motion and sensation. Beyond the great fact that the brain is the organ which is directly or indirectly diseased in insanity, we are yet in the most profound state of ignorance regarding the intimate pathology of this condition. *Post mortem* examination reveals morbid conditions of vascularity, or various forms of degeneration, in the vessels, nerve-cells, neuroglia, etc.; but, with the exception, perhaps, of general paralysis of the insane, we have yet to find out whether there are any morbid appearances specially characteristic of special forms of mental derangement, or whether there is a definite relation between the locality of the lesion and the symptoms observed. We cannot even be sure whether many of the changes discovered are the cause or the result of the disease, or whether the two are the conjoint results of a common cause.

It is no disparagement of the many valuable researches which have been made into the pathology of insanity, to say that we are only beginning to learn its rudiments. Until the various morbid appearances discoverable in the brains of the insane are translatable into their subjective signification, the morbid anatomy and pathology of insanity run in parallel lines, which never meet. A concrete or incorporate mental pathology distinct from mere speculation will only be furnished when we can give the subjective equivalents of morbid appearances, or, conversely, the anatomical substrata of subjective states. It will not, I think, be denied that we are yet a long way from having reached this desirable consummation of our researches.

From the fact that large tracts of the brain-cortex may be disorganised without causing any very evident mental disturbance, and from the further fact that any *one* part of the brain may be so destroyed with a like negative result, the conclusion has been drawn by Flourens and others, that there is no localisation or differentiation of function, but that each part of the encephalon is a microcephalon, capable of itself of performing all the functions pertaining to the whole. Supposing the conclusions at all justifiable *quâ* mind, it would be altogether unwarrantable to extend this, as has been done frequently, to physiological function.

If we look at this matter a little more closely, we shall find that not merely extensive lesions in one hemisphere may be latent as regards mental symptoms, but even a whole hemisphere may be disorganised with a like negative result. If, however, *both* sides of the brain be disorganised, the annihilation of mind is complete. The logical deduction from these facts therefore is, not that there is no special localisation of function, but that, as far as the fundamental powers of mind are concerned—sensation, emotion, volition, and intellect—one hemisphere is sufficient.

To show that there is no localisation of mental function, it is necessary to demonstrate that the *same* parts may be destroyed in *both* hemispheres without producing mental disturbance. But has this ever been shown? I cannot find the faintest approach to evidence which would justify such a conclusion. That mental symptoms or mental deficiencies have not been recorded in cases of bilateral cerebral lesions, is a negative statement of very little value. Unless a man becomes so demented as to neglect the ordinary wants of nature, or so furious, maniacal, or irrational as to require restraint, there are few engaged in the practice of medicine who think of inquiring narrowly into a patient's mental state; and, even if more attention were directed towards this subject, are we in possession of any means of accurately gauging the mental condition of an individual, so as to be certain that it has altogether escaped damage notwithstanding the presence of a cerebral lesion? I see little to justify and much to contradict such an assumption. A man may not be incapacitated for the ordinary duties of life; but that his mental powers are altogether unscathed even by an unilateral lesion, I venture to question.

And, if it is difficult to test the mental condition in a human being, how much more difficult must it be in the case of the lower animals? And yet, from the way in which some have treated this question, one would be led to believe that nothing was more simple. Flourens' conclusions are, I think, answerable for many erroneous notions which have long dominated cerebral physiology and pathology. One great fallacy has been the assumption that the results of experiments on frogs, pigeons, and other animals low in the scale, are at once capable of application to man without qualification: an assumption which vitiates the conclusions of numerous physiologists of the present day. The very fact that there exist such patent differences between the effects of destruction of the cerebral hemispheres in different orders of animals ought, one would think, to inspire caution in the application to man of results obtained only by experiments on the brains of animals low down in the scale. Physiology should take a more comprehensive

view, and in particular not neglect the facts of clinical medicine and human pathology. To do so in the case of the functions of the brain would, indeed, be the play of *Hamlet* with the Prince of Denmark left out.
